occam 2 Toolset
Reference Manual
## Contents overview

### Contents

**Preface**

**Tools**

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>oc</code></td>
<td>Describes the occam 2 compiler.</td>
</tr>
<tr>
<td>2</td>
<td><code>occonf</code></td>
<td>Describes the configurer which generates configuration binary files from configuration descriptions.</td>
</tr>
<tr>
<td>3</td>
<td><code>icollect</code></td>
<td>Describes the code collector which generates executable code files.</td>
</tr>
<tr>
<td>4</td>
<td><code>idebug</code></td>
<td>Describes the network debugger. Lists the symbolic functions and Monitor page commands at machine level.</td>
</tr>
<tr>
<td>5</td>
<td><code>idump</code></td>
<td>Describes the memory dumper tool which dumps root transputer memory for post mortem debugging.</td>
</tr>
<tr>
<td>6</td>
<td><code>iemit</code></td>
<td>Describes the memory configurer tool which helps to configure the transputer memory interface.</td>
</tr>
<tr>
<td>7</td>
<td><code>ieprom</code></td>
<td>Describes the EPROM formatter tool which creates executable files for loading into ROM.</td>
</tr>
<tr>
<td>8</td>
<td><code>ilibr</code></td>
<td>Describes the toolset librarian which creates libraries from compiled code files.</td>
</tr>
<tr>
<td>9</td>
<td><code>ilink</code></td>
<td>Describes the toolset linker which links compiled code and libraries into a single unit.</td>
</tr>
<tr>
<td>10</td>
<td><code>ilist</code></td>
<td>Describes the binary lister which displays binary files in a readable form.</td>
</tr>
<tr>
<td>11</td>
<td><code>imakef</code></td>
<td>Describes the Makefile generator which creates Makefiles for toolset compilations.</td>
</tr>
<tr>
<td>12</td>
<td><code>imap</code></td>
<td>Describes the map tool which generates a memory map for an executable file.</td>
</tr>
<tr>
<td>13</td>
<td><code>iserver</code></td>
<td>Describes the host file server which loads programs onto transputer hardware and provides host communication.</td>
</tr>
<tr>
<td>14</td>
<td><code>isim</code></td>
<td>Describes the transputer simulator which allows programs to be run without hardware.</td>
</tr>
<tr>
<td>15</td>
<td><code>iskip</code></td>
<td>Describes the skip loader tool which loads programs onto external subnetworks.</td>
</tr>
</tbody>
</table>
## Appendices

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Toolset standards and conventions</td>
</tr>
<tr>
<td></td>
<td>Describes the conventions and standards of the toolset.</td>
</tr>
<tr>
<td>B</td>
<td>Transputer types and classes</td>
</tr>
<tr>
<td></td>
<td>Describes the meaning and use of transputer types and classes and lists the command line options to select them for the compiler and linker.</td>
</tr>
<tr>
<td>C</td>
<td>ISERVER Protocol</td>
</tr>
<tr>
<td></td>
<td>Describes the server protocol and the ISERVER functions.</td>
</tr>
<tr>
<td>D</td>
<td>ITERM</td>
</tr>
<tr>
<td></td>
<td>Describes the format of the ITERM files.</td>
</tr>
<tr>
<td>E</td>
<td>Bootstrap loaders</td>
</tr>
<tr>
<td></td>
<td>Describes the INMOS bootstrap loading scheme and advises on how it might be customized.</td>
</tr>

  Configured program, boot from ROM, run in ROM .................. 65
3.11 Disabling interactive debugging — 'Y' option .................... 66
3.12 Error messages ........................................................ 67
  3.12.1 Warnings ........................................................... 67
  3.12.2 Serious errors ..................................................... 67
  3.12.3 Fatal errors ........................................................ 72
4 idebug — network debugger ............................................. 73
  4.1 Introduction .......................................................... 73
  4.2 Debugging the root transputer ...................................... 73
    4.2.1 Board wiring .......................................................... 74
    4.2.2 Post-mortem debugging R-mode programs ...................... 74
    4.2.3 Post-mortem debugging T-mode programs ...................... 74
    4.2.4 Post-mortem debugging from a network dump file ........... 75
    4.2.5 Debugging a dummy network ....................................... 75
    4.2.6 Methods for interactive breakpoint debugging .............. 75
4.3 Running the debugger ............................................................. 75
  4.3.1 Toolset file types read by the debugger ......................... 77
  4.3.2 Environment variables .................................................. 78
  4.3.3 Program termination .................................................... 79
4.4 Post-mortem mode invocation ............................................. 79
  4.4.1 Debugging T-mode programs – option ‘T’ ......................... 80
  4.4.2 Debugging R-mode programs – option ‘R’ ......................... 80
  4.4.3 Debugging a network dump file – option ‘N’ .................. 80
  4.4.4 Debugging a previous breakpoint session –
          option ‘M’ ............................................................... 81
  4.4.5 Re-invoking the debugger on single transputer
          programs .................................................................... 81
  4.4.6 Debugging boot from ROM programs ............................... 81
4.5 Interactive mode invocation ................................................ 81
4.6 Function key mappings .......................................................... 82
4.7 Debugging programs on INMOS boards .................................... 82
  4.7.1 Subsystem wiring .......................................................... 82
  4.7.2 Debugging options to use with specific board types .......... 83
  4.7.3 Detecting the error flag in interactive mode ................. 83
4.8 Debugging programs on non-INMOS boards ............................ 84
4.9 Monitor page commands ........................................................ 85
  4.9.1 Command format ......................................................... 85
  4.9.2 Specifying transputer addresses ................................... 85
  4.9.3 Scrolling the display .................................................... 85
  4.9.4 Editing functions ........................................................ 86
  4.9.5 Commands mapped by ITERM ........................................ 86
  4.9.6 Summary of commands ................................................ 86
  4.9.7 Symbolic-type commands .............................................. 88
  4.9.8 Scroll keys ............................................................... 88
  4.9.9 Monitor page command descriptions .............................. 89
  4.9.10 Symbolic-type commands ............................................ 107
4.10 Symbolic functions ............................................................. 108
  4.10.1 Symbolic functions .................................................... 109
  4.10.2 Interactive mode functions ....................................... 111
  4.10.3 Locating functions ..................................................... 112
  4.10.4 Cursor and display control functions ......................... 112
  4.10.5 Miscellaneous functions ............................................. 113
4.11 INSPECT/MODIFY expression language for C ....................... 115
  4.11.1 Syntax not supported ............................................... 115
  4.11.2 Extensions to C syntax .............................................. 115
          Subarrays .............................................................. 115
          Scope resolution operator ........................................ 115
          Hex constants ...................................................... 116
          Address constant indirect ...................................... 116
  4.11.3 Automatic expression pickup ..................................... 116

Host versions

The documentation set which accompanies the occam 2 toolset is designed to cover all host versions of the toolset:

- IMS D7305 – IBM PC compatible running MS-DOS
- IMS D4305 – Sun 4 systems running SunOS.
- IMS D6305 – VAX systems running VMS.

About this manual

This manual is the Toolset Reference Manual to the occam 2 toolset.

The manual provides reference material for each tool in the toolset describing:

- Command line syntax, including an example command line.
- Command line options.
- How to run the tool.
- A list of error messages which may be obtained.

Many of the tools in the toolset are generic to other INMOS toolset products i.e. the ANSI C and FORTRAN toolsets and the documentation reflects this. Examples are given in C.

The appendices provide details of:

- Toolset conventions.
- Transputer types.
- Server protocol.
- ITERM files.
- Bootstrap loaders.
About the toolset documentation set

The documentation set comprises the following volumes:

- **72 TDS 366 01 occam 2 Toolset User Guide**
  
  Describes the use of the toolset in developing programs for running on the transputer. The manual is divided into two sections; 'Basics' which describes each of the main stages of the development process and includes a 'Getting started' tutorial. The 'Advanced Techniques' section is aimed at more experienced users. The appendices contain a glossary of terms and a bibliography. Several of the chapters are generic to other INMOS toolsets.

- **72 TDS 367 01 occam 2 Toolset Reference Manual (this manual)**

- **72 TDS 368 01 occam 2 Toolset Language and Libraries Reference Manual**
  
  Provides a language reference for the toolset and implementation data. A list of the library functions provided is followed by detailed information about each function. Details of extensions to the language are given in an appendix.

- **72 TDS 379 00 Performance Improvement with the INMOS Dx305 occam 2 Toolset**
  
  This document provides advice about how to maximize the performance of the toolset. It brings together information provided in other toolset documents particularly from the Language and Libraries Reference Manual. **Note**: details of how to manipulate the software virtual through-routing mechanism are given in the User Guide.

- **72 TDS 377 00 occam 2 Toolset Handbook**
  
  A separately bound reference manual which lists the command line options for each tool and the library functions. It is provided for quick reference and summarizes information provided in more detail in the Tools Reference Manual and the Language and Libraries Reference Manual.

- **72 TDS 378 00 occam 2 Toolset Master Index**
  
Other documents

Other documents provided with the toolset product include:

- Delivery manual giving installation data, this document is host specific.
- Release notes, common to all host versions of the toolset.

FORTRAN toolset

At the time of writing the FORTRAN toolset product referred to in this document set is still under development and specific details relating to it are subject to change.

INQUEST

The INQUEST products referred to within this document are INMOS window-based debugging and profiling products, which may be bought separately and used with the toolset.

Documentation conventions

The following typographical conventions are used in this manual:

| **Bold type** | Used to emphasize new or special terminology. |
| **Teletype** | Used to distinguish command line examples, code fragments, and program listings from normal text. |
| **Italic type** | In command syntax definitions, used to stand for an argument of a particular type. Used within text for emphasis and for book titles. |
| Braces {} | Used to denote optional items in command syntax. |
| Brackets [] | Used in command syntax to denote optional items on the command line. |
| Ellipsis ... | In general terms, used to denote the continuation of a series. For example, in syntax definitions denotes a list of one or more items. |
| | In command syntax, separates two mutually exclusive alternatives. |
1 oc – occam 2 compiler

This chapter describes the syntax and command line options of the occam 2 compiler oc. The chapter ends with a list of error messages.

Appendix B of the Language and Libraries Reference Manual describes some technical aspects of occam's implementation on the transputer, including the allocation of memory, the machine representation of occam types, and other hardware dependencies.

1.1 Introduction

The toolset compiler implements the occam 2 language targeting to IMS T212, M212, T222, T225, T400, T414, T425, T426, T800, T801, and T805 transputers. Transputer targets are discussed in detail in Appendix B.

oc supports some extensions to the occam 2 language, including: compiler directives; extended channel handling; extended syntax; and low level programming support. These are compiler-dependent and do not extend the definition of the language. Extensions supported by oc are listed in Appendix A of the Language and Libraries Reference Manual.

Each compilation of a program must be targeted at a specific transputer type or class, in one of three execution error modes and with interactive debugging either enabled or disabled. The selection or not of interactive debugging determines the method of channel input/output used by the compiler.

All components of a program to be run on the same transputer must be compiled for compatible target processors, error modes, and method of channel i/o. The compiler provides comprehensive error message information.

Libraries and separately compiled units must be already compiled before any file which references them can itself be compiled. It is the programmer's responsibility to ensure all components of a program are compiled in the correct order and that object code is kept up to date with changes in the source; the linker will object if this is not done. This may be assisted by using a MAKE program in conjunction with the imakef tool. The imakef tool depends on a particular system of file extensions being used. For details of version control using MAKE programs and the imakef tool see Chapter 11. The operation of the compiler in terms of standard file extensions is shown below.

occam source files can contain references to object code libraries, occam source to be included in the compilation, separately compiled occam code, and code produced by compatible compilers for other languages.
1.2 Running the compiler

For a full description and formal definition of the occam 2 language see the occam 2 Reference Manual.

The object file is generated by the compiler in Transputer Common Object File Format (TCOFF). Object files are required to be in this format to be compatible with other tools in the toolset such as the librarian and linker tools.

1.2 Running the compiler

The occam 2 compiler takes as input an occam source file and compiles it into a binary object file. Command line options determine the target transputer for the compilation, the compilation error mode, and other compiler facilities such as alias and usage checking. A target processor and compilation error mode should be specified for each compilation. The compiler default is to produce code for the T414 in HALT mode, and for code of this type the transputer target and error mode options may be omitted.

To invoke the compiler use the following command line:

```
> oc  filename  {options}
```

where: `filename` is the name of the file containing the source code. If you do not specify a file extension, the extension `.occ` is assumed.

`options` is a list, in any order, of one or more of the options given in Table 1.1.

Options must be preceded by `-' for UNIX-based toolsets and `/' for MS-DOS and VMS based toolsets.

Options may be entered in upper or lower case and can be given in any order.

Options must be separated by spaces.

If no arguments are given on the command line a help page is displayed giving the command syntax.
If the compilation is unsuccessful, error messages are displayed giving the name of the file and the number of the line where the error occurred. Compiler error messages are listed in section 1.13.

Example:

UNIX based toolsets:

```
oc -t425 simple
ilink simple.tco hostio.lib -t425 -f occama.lnk
occonf simple.pgm
icollect simple.cfb
iserver -se -sb simple.btl
```

MS-DOS/VMS based toolsets:

```
oc /t425 simple
ilink simple.tco hostio.lib /t425 /f occama.lnk
occonf simple.pgm
icollect simple.cfb
iserver /se /sb simple.btl
```

In this example the source code for a single processor program is compiled for a T425 transputer. The example also shows the commands for linking, configuring, collecting, and loading the program.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transputer type</td>
<td>See Appendix B for transputer type options.</td>
</tr>
<tr>
<td>A</td>
<td>Prevents the compiler from performing alias checking. This option also disables usage checking. The default is to perform alias checking. When alias checking is enabled, the compiler may insert run-time alias checks. Details of alias and usage checking rules are given in Appendix C of the Language and Libraries Reference Manual and also in the Occam 2 Reference Manual.</td>

<td>Disables interactive debugging. See section 1.8. Note: This option also disables the ‘virtual routing’ facilities of the configurer.</td>
</tr>
</tbody>
</table>

Table 1.1 *occam 2* compiler options

### 1.3 Filenames

*occam* source files can be given any legal filename for the host system you are using. The use of the `.occ` extension for *occam* source, and the `.inc` extension for files containing declarations of constants and protocols, is recommended. If an extension is not specified for the input file, the compiler will assume the extension is `.occ`.

Output files are specified using the ‘o’ option. If you do not specify a filename, the input filename is used (minus any directory name) and a `.tco` file extension is added. In this case the file will be placed in the current directory i.e. the directory from which the compiler is invoked.

If you use the Makefile generator tool *imakef* you *must* use the extensions described in section 11.3.

### 1.4 Transputer targets

The compiler produces code for the IMS T212, M212, T222, T225, T400, T414, T425, T426, T800, T801, and T805 transputers. Command line options are provided to specify the processor type for the compilation. If more than one processor type is specified, the compilation will terminate immediately and an error message will be displayed. If no target is specified the compilation defaults to a T414 target.

Programs may also be targeted at transputer *classes*, which enable the same code to be run on groups of related transputer types.

A description of transputer types and classes can be found in Appendix B.
1.5 Error modes

The execution error mode determines the behavior of a program if it fails during execution. There are two main modes; HALT system and STOP process. There is also a special mode called UNIVERSAL. Command line options are provided to select the error mode for the compilation. Specifying more than one error mode will cause the compilation to terminate immediately and an error message will be displayed.

The execution behavior of programs compiled in the different modes is as follows:

**HALT**
When an error occurs in the program the transputer halts. This is useful for developing and debugging systems and is the default mode. For errors to be detected correctly the server must be invoked with the 'SE' option.

**STOP**
When an error occurs the system behaves like the OCCAM STOP process, that is the process causing an error does not continue. Other processes continue until they become dependent upon the stopped process. This ensures that a failure in one process does not automatically produce failure in other processes. Using this mode it is possible to build a system with redundancy and enable a system to run even if parts of the program fail or processes fail because a time out is exceeded.

**UNIVERSAL**
UNIVERSAL mode enables the user to compile code that may be run with either HALT or STOP mode in effect. The decision about which mode to adopt need not be taken until the separately compiled modules are combined into a linked object file. On linking the modules, any code that has been compiled in UNIVERSAL error mode will adopt the error mode of the other modules i.e. either HALT mode or STOP mode. HALT and STOP error modes may not be combined on the same processor.

Code compiled in either HALT or STOP mode may call code compiled in UNIVERSAL mode, however, code compiled in UNIVERSAL mode may only call code which has also been compiled in UNIVERSAL mode. It cannot call code which has been compiled in HALT or STOP mode.

All separately compiled units for a single processor must be compiled for compatible error modes. Where a library is used the module with the appropriate error mode will be selected.

Compilation error modes and their effects are described in more detail in section 5.3 of the *occam 2 Toolset User Guide*.

1.6 Enable/Disable Error Detection

By default the compiler inserts code to execute run-time checks for errors it cannot detect at compile time. In some circumstances it may be desirable to omit the run
time error checking in one part of a program, for example, in a time-critical section of code, while retaining error checks in other parts of a program, for debugging purposes. Three command line options are provided to enable the user to control the degree of run-time error detection performed; they are the 'K', 'u' and 'NA' options.

The compiler option 'K' disables the run-time range checks for the module being compiled. Range checking only includes checks on array subcripting and array lengths.

The compiler option 'u' prevents the compiler from inserting any code to explicitly perform run-time checks. This will disable run-time checks associated with type conversion, shift operations, array access, range validation and replicated constructs such as SEQ, PAR, IF, and ALT. Runtime checks implicit in the transputer instructions are still performed, for example, add will automatically check for arithmetic overflow.

Note: The 'u' option can be used to remove unnecessary runtime checks from code which is fully debugged and known to be error-free. It is equivalent to implementing the occam error mode UNDEFINED.

The 'NA' option prevents the compiler from inserting any code to check calls to ASSERT. In effect, each ASSERT behaves like SKIP. Any calls to ASSERT which can be evaluated at compile time will still be checked.

The effect of using these options is described in detail in section 5.3.2 of the occam 2 Toolset User Guide.

1.7 Enabling/disabling warning messages

There are several command line options which allow the user to either enable or disable the generation of certain warning messages produced by the compiler:

- The NWCA option disables the generation of warning messages when CHAN OF ANY is used. CHAN OF ANY is now considered obsolete and replacement with named protocols of type ANY is recommended. See section A.2.3 of the occam 2 Toolset User Guide.

- The NWGY option disables the generation of warning messages when the GUY construct is used. GUY is now considered obsolete and ASM should be used instead.

- The NWP option disables warning messages being generated when parameters to procedures are not used.

- The NWU option disables warning messages being generated when variables or routines are not used.

- The WALL option turns on all warnings which are controlled from the command line i.e. it is currently equivalent to WD, WO and WQUAL.
• The WD option provides a warning whenever a name is descoped, for example when a name is used twice and one occurrence of it is hidden within an inner procedure. See section 8 of the occam 2 Reference Manual for details of occam scope rules.

• The WO option provides a warning whenever a run-time alias check is generated i.e. to check that variables do not overlap. These checks generate extra code and the user may wish to be alerted to this.

• The WQUAL option enables software quality warnings. Currently these include a warning about incorrect positioning of PLACE statements and a warning about unused CASE options.

Section 1.13.1 lists the warning messages which are affected by these options.

### 1.8 Support for debugging

The occam 2 compiler supports interactive debugging with idebug by default. When interactive debugging is enabled the compiler will generate calls to library routines to perform channel input and output, rather than using the transputer’s instructions.

Interactive debugging may be disabled using the compiler ‘x’ option. This option forces the compiler to use sequences of transputer instructions for channel input and output, resulting in faster code execution. Note: This option also disables the ‘virtual routing’ facilities of the configurer.

Code which has interactive debugging disabled may call code which has interactive debugging enabled, but not vice versa. However, when interactive debugging is disabled in one part of the program this will prevent the interactive features of the debugger being used on the program as a whole.

The compiler ‘D’ option disables the generation of full debugging data. Minimal debugging data remains to allow the debugger to backtrace through the code. This option enables library code to be created without the overhead of debugging data.

### 1.9 Separately compiled units and libraries

Any group of one or more occam procedures and/or functions may be compiled separately provided they are completely self-contained and make no external references except via their parameters or compiler directives. Separate compilation is used to reduce the need for recompilation, and to split compilations into smaller parts. Separately compiled code is known as a compilation unit.

Any collection of compilation units may be made into a library using the librarian ilibr (see chapter 8). Libraries and compilation units differ in the following way:

- Libraries are selectively loaded as required by the transputer type and error mode of the compilation, whereas separately compiled units are always loaded. If a unit containing incompatible code is used an error is generated, whereas libraries containing incompatible code are ignored.
All separate compilation units and libraries must be compiled before the program that references them is itself compiled. An easy way to ensure this is to use the toolset Makefile generator `imakef` with a suitable Make utility. For more details see Chapter 11.

### 1.10 Code insertion using ASM

Two compiler options are provided to enable the compiler to recognize transputer instructions inserted into source code using the `ASM` construct. The 'G' option permits use of a limited range of sequential instructions whereas the 'W' option permits use of the full range of transputer instructions. For further details see Appendix D of the *User Guide*. Transputer instructions are listed in Appendix C of the *User Guide*.

### 1.11 Memory map

The compiler may be instructed, via the `mapfile` option, to produce a map of workspace for each function defined in the file. The file contains information which may assist the user during program debugging. The map is written to the file `mapfile`.

The file consists of a series of workspace maps, one for each routine, giving details of workspace requirements. These are followed by a section map listing details of procedures and functions.

---

**Map of code and data for source file simple.occ**

---

Created by occam 2 compiler Beta Vn 2.01.79 (19:33:49 Oct 20 1992) (SunOS-S un4)

Target processor : T4

Error mode : HALT

Map of workspace

```
Routine : simple
Variable name Offset (words)
$anon0 4
length 5
result 6
buffer 10
```

```
Formal parameter name Offset (words)
fs 8
t 9
memory 10
<hidden_dimension> 11
<vectorspace_pointer> 12
```

Workspace size = 53 words, Vectorspace size = 128 words

Section map

```
Section name : text%base : size = 164 bytes
Name Type Offset (bytes)
simple code 3
```

---

*Figure 1.1 Example compiler map*
The file is generated in text format. The following information is present:

- The name of the source file for which the map of code and data is being produced. The full pathname will be given if it exists.
- Version data for the compiler.
- The target transputer of the compilation, T805, T400, etc.
- The error mode of the compilation.
- Name of the routine for which the map of workspace is being produced. Items in the workspace map are given in ascending order of workspace offset.
  - List of local variables giving their offset (in words) into the routine's workspace. This list may include temporary variables introduced by the compiler.
  - List of formal parameters giving their name and offset (in words) into the routine's workspace. Parameters added by the compiler may also be listed, see Table 1.2.
  - The workspace and vector space requirements of the routine in words. This includes the requirements of all nested calls but not the four word overhead introduced by the transputer call instruction.
- Name of the section for which the section map is being produced. Items in the section map are given in ascending order of section offset.

Details of how the compiler allocates space for variables are given in section B.1 of the Language and Libraries Reference Manual.

<table>
<thead>
<tr>
<th>Formal parameter</th>
<th>hidden dimension</th>
<th>vectorspace pointer</th>
<th>static link</th>
</tr>
</thead>
</table>

Table 1.2 Parameters inserted by compiler

Note: The message "No local variables" may be displayed if no user variables are found, however, compiler temporaries may have been assigned to workspace. In addition some compiler temporaries may not be listed in the map file.

Information generated in the compiler map file may be extracted by the imap tool. This tool can be used to produce a memory map for the program after it has been compiled, linked and collected. See chapter 12.

1.12 Compiler directives

The occam compiler supports a number of directives that allow the programmer to customize a compilation. All are extensions to the language. If the compiler 'I' option is used directives are displayed on the screen as the compilation proceeds.
Directives supported are:

- **#INCLUDE** inserts OCCAM source code
- **#USE** references separately compiled units and libraries
- **#IMPORT** references non-OCCAM compiled code
- **#COMMENT** inserts comments in object code
- **#OPTION** allows selection of compiler options from within source text
- **#PRAGMA** miscellaneous extensions, including support for the import of other languages, code placement in RAM, and disablement of checks on specific variables.

### 1.12.1 Syntax of compiler directives

Filenames referred to in compiler directives must be enclosed in double quotes (""). Files are located according to the search strategy defined in section A.4 of the *Tools Reference Manual*.

If double quotes are to be used within a directive, the double quote character must be preceded by an asterisk (*).

The scope of directives are defined, like declarations of constants and protocols, by the level of indentation in the OCCAM source.

When `imakef` is used, if a filename in a #USE, #INCLUDE or #IMPORT directive does not already have an extension then `imakef` will add the appropriate extension depending upon the target that it is attempting to build. If you use the Makefile generator tool `imakef` you must use the extensions described in sections 11.3 and A.6 of the *Tools Reference Manual*.

### 1.12.2 #INCLUDE

The #INCLUDE directive inserts the contents of a named file at the point in the program source where the directive occurs, with the same indentation as the directive.

#INCLUDE files can be used by any number of programs, including separately compiled units, and are commonly used to share common declarations of constants and protocols between several programs.

To track file dependencies within included files use of the `imakef` tool is recommended.

The syntax of the #INCLUDE directive is as follows:

```
#INCLUDE "filename" [comment]
```

where: `filename` is the name of the file to be included. The extension must be supplied.

`comment` is any text preceded by the characters `--`.
The first text after the directive must be the filename enclosed within double quotes (""). All other text on the line is ignored and may be used for comments. For example:

```
#include "header.inc"
```

Included files may be nested to any depth.

1.12.3 #USE

The #USE directive allows separately compiled OCCAM units and libraries (in TCOFF format) to be referenced from OCCAM source. The file referenced by the #USE directive must be compiled for a compatible processor type and compilation mode as the main program, and should be made available in all modes for which the program will be compiled.

The compiler ignores all library modules compiled with a processor type or compilation mode incompatible with the current compilation. A library may be used in any number of separately compiled units or other libraries, provided that each unit contains the #USE directive.

Any names in the library which do not conform to OCCAM syntax, and which have not been translated by means of a TRANSLATE pragma will be ignored. Note: this means that a TRANSLATE pragma must precede its related #USE directive. See section 1.12.7.

The syntax of the #USE directive is as follows:

```
#use "filename" [comment]
```

where: `filename` is the name of the object code file. The object file can be a compiled (.tco) or library (.lib) file. If you omit the file extension, the compiler adds the extension of the output file. This will be .tco unless you specified an output filename using the 'o' option.

`comment` is any text preceded by the characters '--'.

The first text after the #USE directive must be the filename, which must be enclosed within double quotes ("""). All other text on the line is ignored and may be used for comments. For example:

```
#include "module"
#include "library.lib"
#include "module.tco"
#include "module.t2h"
```

1.12.4 #IMPORT

The #IMPORT directive allows code produced by compatible non-OCCAM compilers to be referenced from OCCAM programs. It operates in the same way
as \#USE except that the code that is imported is marked as ‘foreign’ and not included in makefile searches.

**Note:** The code imported by \#IMPORT must be compatible with the current toolset linker ilink.

The syntax of the \#IMPORT directive is as follows:

\[
\textbf{\#IMPORT} \quad \textit{“filename” \ [comment]} \\
\textit{filename} \quad \text{is the name of the compiled equivalent OCCAM process. If no extension is given the .tco extension is assumed.} \\
\textit{comment} \quad \text{is any text preceded by the characters ‘\---’}. \\
\]

The first text after the \#IMPORT directive must be the file name, which must be enclosed within double quotes ("). All other text on the line is ignored and may be used for comments.

An example of how to use the \#IMPORT directive is given below:

\[
\textbf{\#IMPORT} \quad \textit{“centry.lib” \ -- \ C interface code} \\
\textit{PROC.ENTRY(fs, ts, flag, ws1, ws2, in, out)} \quad \text{-- call C language program} \\
\]

The parameters supplied in the program call, flag, ws1, ws2, in, and out are those of the type 2 procedural interface. The program must be linked with C libraries centry.lib and libc.lib. Details of this method of mixed language programming can be found in section 11.2 of the User Guide.

Details of an alternative method of mixed language programming where non-OCCAM programs are called directly using library functions can also be found in Chapter 11 of the User Guide.

**1.12.5 \#COMMENT**

The \#COMMENT directive allows comments to be placed in the object code. These comments can be read by the binary lister tool ilist.

The syntax of the \#COMMENT directive is as follows:

\[
\textbf{\#COMMENT} \quad \textit{“string” \ [comment]} \\
\textit{string} \quad \text{is the text of the comment. Comments must be enclosed in double quotes following the \#COMMENT directive. Comments cannot be split over more than one line.} \\
\]
Comments may not appear at the exact position in the object code corresponding with the source code directive, but the sequence of comments in the file is always maintained. Comments included by \#COMMENT are stripped from the object code when it is linked or made bootable.

The main use for the \#COMMENT directive is in libraries or other pre-compiled code where it can be used to indicate a version number, record dependencies on other libraries, and hold copyright information. The comment strings can then be displayed using ilist.

An example of how to use the \#COMMENT directive is given below:

```plaintext
PROC my.lib ()
    \#COMMENT "My library V1.3, 18 May 1988"
    \#COMMENT "Copyright me 1988"
    SEQ
        ... library source
#COMMENT acts like \#PRAGMA COMMENT. For example:
    \#COMMENT "string"

is equivalent to:
    \#PRAGMA COMMENT "string"

See also section 1.12.7.

1.12.6 \#OPTION

The \#OPTION directive allows you to specify certain command line options within the source text of a compilation unit, so that they apply only to that unit. Options specified in this way are simply added to the command line when the compiler is invoked.

Arguments to \#OPTION are those that relate directly to the source, namely:

- A – disable alias (and usage) checking.
- E – disable the compiler libraries.
- G – allow sequential code inserts (via the ASM construct).
- K – disable the insertion of run-time range checks.
- N – disable usage checking.
- U – disable the insertion of any run-time error checks.
- V – disable separate vector space usage.
- W – enable full code inserts, (via the ASM construct).
- Y – disable interactive debugging.

Specifying any other option produces an error. Descriptions of the arguments can be found in Table 1.1.
#OPTION directives can only appear in the file to which they apply; they cannot be nested in an included file. #OPTION directives must also be the first non-blank or non-comment text in the source file. If they are found at any other position in the file an error is reported.

The syntax of the #OPTION directive is as follows:

```
#OPTION "optionname {optionname}" [comment]
```

where: `optionname` is any option permitted in a #OPTION directive. Spaces within the double quotes are ignored. No option prefix character is required in the syntax and none should be specified.

`comment` is any text preceded by the characters '---'.

The first text after the #OPTION directive must be the list of options enclosed in double quotes. All other text on the line is ignored and may be used for comments.

An example of how to use the #OPTION directive is given below. In the example the unit does not require usage checking but contains transputer code inserts from the restricted set.

```
-- This compilation unit requires sequential code inserts and does not pass the usage check.

#OPTION "G N"

PROC x ()
  ... body of procedure
```

The #OPTION directive should only be used for compiler options that are always required for a specific compilation.

**UNDEFINED** error mode

#OPTION "U" can be used to implement the occam error mode UNDEFINED.

1.12.7 #PRAGMA

The #PRAGMA directive is provided to reference segments of code for mixed language compilations and/or linking functions:

```
#PRAGMA pragma-name {optional values} [comment]
```

where: `pragma-name` may be one of:

- COMMENT
- EXTERNAL
- LINKAGE
- PERMITALIASES
- SHARED
- TRANSLATE
optional values may be specified for each type of pragma. The values that the options may take are specific to the pragma being used; they are described below.

comment is any text preceded by the characters '---'. All pragma types may have a comment appended to them.

#PRAGMA COMMENT "string" [comment]

#PRAGMA COMMENT allows comments to be placed in the object code. These comments can be read by the binary lister tool ilist. In all respects #PRAGMA COMMENT acts like #COMMENT (see section 1.12.5).

#PRAGMA EXTERNAL "declaration" [comment]

This directive allows access to other language compilations. declaration is a PROC or FUNCTION declaration, with formal parameters which correspond to the required calling convention. This is followed (within the string) by two numbers in decimal, indicating the number of workspace slots (words) and optionally the number of vectorspace slots to reserve for that call. The number of vectorspace slots defaults to 0. The number of the workspace slots should not include those needed to set up the parameters for the call. Note: that if the vectorspace requirement is zero, then no vectorspace pointer parameter will be passed to the routine. It is important to ensure that enough space is allocated, both for workspace and vectorspace, because the compiler cannot check for overruns.

The syntax of the declaration is as follows:

formal procedure or function declaration = workspace [, vectorspace]

Examples:

#PRAGMA EXTERNAL "PROC p1 (VAL INT x, y) = 20"
#PRAGMA EXTERNAL "PROC p2 (VAL INT x, y) = 20, 100"
#PRAGMA EXTERNAL "INT FUNCTION f1 (VAL INT x, y) = 50"
#PRAGMA EXTERNAL "INT FUNCTION f2 (VAL INT x, y) = 50, 0"

The procedure or function name is the name by which the external routine is accessed from the OCCAM source. It is also the name which will be used by the linker to access the external language function, though this may be modified by use of the TRANSLATE pragma.

#PRAGMA LINKAGE ["section-name"] [comment]

This pragma enables the user to identify modules that he wishes to be placed in on-chip RAM. The user may then prioritize the order in which these modules are linked together by using a linker directive. On-chip RAM is allocated to workspace first and then to code. Provided there is enough RAM available it should be possible for commonly used subroutines to be processed in the on-chip RAM. This should make the program run faster.
Normally the compiler creates the object code in a section named "text%base". The #PRAGMA LINKAGE directive causes the compiler to change the name of the section to that supplied in the string. If the directive is used but no section name is provided by the user, the compiler supplies the priority section name "pri%text%base". More than one module may take the section name "pri%text%base".

A linker directive is used to change the order in which code modules are linked together, by supplying a list of prioritized section-names, see section 9.4.6. Provided that the linker does not encounter any linker directives listing section-names, it will place "pri%text%base" modules first. Any unnamed modules are added in an undefined order at the end of the linked unit.

Note: floating point routines such as REAL32OP and REAL32OPERR are automatically optimized by the compiler by placing them in a "pri%text%base" section.

The #PRAGMA LINKAGE directive should appear at the start of the source code, immediately following the #OPTION directive, if one is present.

For example:

```
#OPTION "N"
#PRAGMA LINKAGE "PRIORITY1" - highest priority

#PRAGMA PERMITALIASES variable.list [comment]
```

This pragma disables alias checking for specified variables. It may be applied to normal variables, abbreviations and RETYPES, or non-VAL formal parameters.

This pragma must immediately follow the declaration of the variable it refers to, e.g.

```
int x, y, z :
PRAGMA PERMITALIASES x ..... is correct
PRAGMA PERMITALIASES y ..... is incorrect
```

```
int x :
int y :
PRAGMA PERMITALIASES x ..... is incorrect
```

```
#PRAGMA SHARED variable.list [comment]
```

This pragma disables usage checking for specified variables. It may be applied to normal variables, abbreviations and RETYPES, or non-VAL formal parameters.

This pragma must immediately follow the declaration of the variable it refers to, in the same manner as the pragma PERMITALIASES, see above.
1.13 Error messages

#PRAGMA TRANSLATE identifier "string" [ comment ]

This is used to enable linkage with routines whose entry point names do not correspond to OCCAM syntax for identifier names; both imported names to be called by this compilation unit and exported names defined in this compilation unit. An entry point is a name which is visible to the linker. Thus procedures and functions declared at the outermost level of a compilation unit are entry points, whereas nested procedures and functions are not.

Any entry point defined in the compilation unit whose name matches identifier is translated to string when inserted into the object file, and hence can only be referenced as string when linking. String may not contain the NUL character ('\#00').

Any entry points in #USEd libraries and other compilation units whose names match string can be referred to within the compilation unit as identifier. This also applies to identifiers defined by EXTERNAL pragmas. TRANSLATE pragmas must precede any reference to their identifier.

For example:

```
#PRAGMA TRANSLATE c.routine "c_routine"
#PRAGMA EXTERNAL "PROC c.routine () = 100"
```

1.13 Error messages

All messages produced by the compiler are in the standard toolset format. Details of the format can be found in section A.7. Messages are generated at severity levels Information, Warning, Error, and Fatal. No messages are generated at severity level Serious.

No object files are generated if an error occurs.

Notes

1. The compiler libraries are automatically loaded if required, unless the compiler 'E' option is used.

2. The compiler finds the compiler libraries by searching the path specified by the host environment variable ISEARCH. The most common cause of a compiler library error is failure to set up this logical name correctly.

The error messages listed here are those which are produced by incorrect use of the compiler, caused for instance by failing to specify command line options correctly. The compiler also reports all syntax and semantic errors found in the program; these messages are not listed here as they are language specific and therefore outside the scope of this document.

1.13.1 Warnings

Badly formed #PRAGMA name directive

The pragma directive does not conform to the required syntax.
CHAN OF ANY is obsolete: use PROTOCOL name IS ANY

The CHAN OF ANY construct is now considered obsolete. The ability to define a named protocol as in PROTOCOL name IS ANY provides greater security and should be used in preference. This warning may be disabled by means of the NWCA command line switch.

GUY construct is obsolete: use ASM instead

The GUY construct is obsolete; the ASM construct provides greater security and should be used in preference. This warning message may be disabled by means of the NWGY command line switch.

name is not used

The named variable is never used. This warning may be disabled by the NWU command line option.

Name name descopes a previous declaration

This name descopes another name which has already been declared. This warning is only enabled when the WD command line option is used.

No compatible entrypoints found in name

The named library contains no routines which may be called from this error mode and/or processor type.

Obsolete channel type conversion: use channel RETYPE

The ability to pass a CHAN OF ANY as an actual parameter to a procedure whose formal parameter is a different channel type is obsolete. A channel RETYPE should be inserted before the call to make the type conversion explicit. This warning may be disabled by means of the NWCA command line switch.

Parameter name is not used

The named parameter is never used. This warning may be disabled by the NWP command line option.

Placement expression for name clashes with virtual routing system

The named variable is placed on one of the transputer links. This may interfere with the INMOS interactive debugging system or the virtual routing system.

Placement expression for name wraps around memory

The calculation of the machine address for this variable has overflowed; the truncated address is used.

72 TDS 367 01

March 1993
PLACEment must immediately follow declaration of name

There should be no other variable declarations between a variable's own declaration and any modifying PLACE statement. This warning is enabled for PLACE statements by the WQUAL command line switch.

Possible side-effect: PLACED variable name

A PLACED variable has been declared inside a VALOF. The compiler cannot ensure that this cannot cause a side-effect.

Possible side-effect: instanced PROC has PLACED variable name

A PLACED variable has been declared inside a PROC which is called from within a VALOF. The compiler cannot ensure that this cannot cause a side-effect.

PORT name must be placed

A PORT type must be placed using an allocation. See the occam 2 Reference Manual for further details.

Routine name is not used

The named routine was never called. This warning may be disabled by the NWU command line option.

Run-time disjointness check inserted

number Run-time disjointness check inserted

The compiler has inserted run-time checks to ensure that variables are not aliased (i.e. that they do not overlap). This warning is only enabled when the WO command line option is used.

TRANSLATE ignored: Module containing name has already been loaded

The #TRANSLATE pragma must precede any #USE of a library containing that string.

TRANSLATE ignored: Name name has already been used

You may not specify multiple translation strings for the same name.

TRANSLATE ignored: String contains NUL character

The specified string for a #TRANSLATE pragma may not include a NUL (zero) byte.

TRANSLATE ignored: String name has already been used

You may not specify multiple names to be translated to the same string.
Unknown #PRAGMA name: name

The pragma name is ignored.

Using length 'name' in array part of counted array input is obsolete

The language no longer permits using the length part of a counted array input to appear in the array part. It does however allow the following special case to be written where the length only appears as the length of a slice:

\[ \text{channel.exp} ? \text{name} :: [ \text{array.exp FROM 0 FOR name \} ] \]

This is transformed by the compiler into the equivalent construct:

\[ \text{channel.exp} ? \text{name} :: \text{array.exp} \]

The former construct is obsolescent and programs should be re-written to use the latter form.

Workspace clashes with variable PLACED AT WORKSPACE number

A variable has been placed at the workspace address number, and this clashes either with another placed variable, or with the compiler's workspace allocation requirements.

1.13.2 Errors

Bad object file format

Library or separately compiled procedure object code is not in the correct format. The code may not have been linked correctly, or the file may have become corrupted.

Badly formed compiler directive

A compiler directive following # was not recognized.

Badly formed #EXTERNAL directive

The number of workspace slots to reserve for the call has not been specified or negative workspace or vector space slots have been specified in error.

Cannot open file "string"

File is missing, or file system error.

Cannot open output file

The object file could not be opened. File system error.
Cannot open output file *(string)*

The file given as parameter to the command line R option could not be opened.

Cannot open source file

The source file cannot be opened. Either it does not exist, or there is a file system error.

Code buffer full *(nnn* bytes); use command line to increase buffer size

The compiler has an internal buffer for code which is about to be placed into the object file; this has overflowed. The CODE command line option may be used to increase the size of this buffer.

Code insertion is not enabled

You must use the G or W options to enable assembler inserts.

Descriptor has incorrect format

Library or separately compiled procedure object code is not in the correct format. The code may not have been linked correctly, or the file may have become corrupted.

Duplicate error modes on command line

Multiple error modes may not be specified for the compilation.

Duplicate processor types on command line

Multiple processor types may not be specified for the compilation.

Expected string after #COMMENT

#COMMENT directive must be followed by a string containing the comment.

Expected string after #OPTION

#OPTION directive must be followed by a string containing the options .

‘Filename’ is not a valid object file

Library or separately compiled unit object code is not in the correct format. The code may not have been linked correctly, or the file may have become corrupted.

Instruction is not available in current code insertion mode

You must set the W option in order to use this instruction.
Instruction is not available on target processor

The given instruction is not present in the target instruction set.

Invalid command line option (string)

The user specified an unrecognized command line option.

Missing filename

Filename is missing on #USE, #INCLUDE or #IMPORT directive.

Missing object file name

There is no object file name parameter to the command line O option.

Missing output file name

There is no output file name parameter to the command line R option.

No filename given

No source file was specified on the command line.

number reading source file

File system error. The source file or an include file could not be read. number is the host file system error number.

number writing to object file

File system error. The object file could not be written to. number is the host file system error number.

Option in illegal position

Only one #OPTION directive is allowed in a file, and it must be on the first non-blank or non-comment line in a file.

PRAGMA must immediately follow declaration of name

There should be no other variable declarations between a variable's own declaration and any modifying #PRAGMA.

Run out of symbol space

The source compilation unit is too large to be compiled.

Unrecognised option "char" in option string

Incorrect compiler options specified after a #OPTION directive.
This chapter describes the configurer tool `occonf` that configures code for transputer networks. It describes the command line syntax and explains how the tool is used to generate a configuration data file for input to the code collector tool. The chapter ends with a list of error messages.

2.1 Introduction

The configurer takes a configuration description created using the transputer configuration language and produces a configuration data file which `icollect` uses to generate bootable code for a transputer network. The bootable code may be generated in a specific error mode.

A configuration description describes how code is to be run on a network of transputers. It consists of separate definitions of the software and hardware networks, and a mapping description which defines how the software will be placed on the processor network. Using this description the configurer allocates code to particular processors and performs wide ranging consistency checks on the mapping of software to hardware. Chapter 6 in the User Guide explains how to write a configuration description.

Linked modules and libraries which are referred to by a configuration description must be already compiled and linked before any file which references them can itself be configured.

The operation of the configurer tool is illustrated below. Files are represented in terms of their standard toolset file extensions.

`occonf` produces two output files:

- the main configuration data file (.cfb) for the collector
- a file (.clu) containing executable code packets, used by the collector.
2.2 Running the configurer

To run the configurer use the following command line:

```
occonf filename {options},
```

where: `filename` is the configuration description file. If no file extension is specified, the extension `.pgm` is assumed. Only one file may be specified.

`options` is a list of one or more options from Table 2.1.

| Options must be preceded by `-' for UNIX-based toolsets and `/` for MS-DOS and VMS based toolsets. |
| Options may be entered in upper or lower case and can be given in any order. |
| Options must be separated by spaces. |

If no arguments are given on the command line a help page is displayed giving the command syntax.

**Examples of use:**

**UNIX based toolsets:**

```
oc simple
ilink simple.tco hostio.lib -f occama.lnk
occonf simple.pgm
icollect simple.cfb
iserver -sb simple.btl -se
```

**MS-DOS and VMS based toolsets:**

```
oc simple
ilink simple.tco hostio.lib /f occama.lnk
occonf simple.pgm
icollect simple.cfb
iserver /sb simple.btl /se
```

2.3 Boot-from-ROM options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RA</strong></td>
<td>Creates a file suitable for a boot-from-ROM application in which the code and data are both loaded into RAM. Interactive debugging must be disabled using the Y option.</td>
</tr>
<tr>
<td><strong>RE</strong></td>
<td>Enables re-ordering of code and data layout in memory, using the <code>order.code</code>, <code>order.vs</code> and <code>order.ws</code> attributes. Also enables the <code>location.code</code>, <code>location.ws</code>, and <code>location.vs</code> attributes. See section 2.6. This option disables the ability to use <code>idebug</code> but not the INQUEST debugger.</td>
</tr>
<tr>
<td><strong>RO</strong></td>
<td>Creates a file suitable for a boot-from-ROM application in which the code is loaded into ROM and the data is loaded into RAM. Interactive debugging must be disabled using the Y option.</td>
</tr>
<tr>
<td><strong>S</strong></td>
<td>Produces code in STOP error mode. See section 2.4.</td>
</tr>
<tr>
<td><strong>U</strong></td>
<td>Disables the insertion of all extra run-time error checking. The default is to insert run-time error checks. This is a 'stronger' option than K, and can be used to implement the OCCAM UNDEFINED error mode. See section 2.5.</td>
</tr>
<tr>
<td><strong>V</strong></td>
<td>Prevents the configurer from producing code which has a separate vector space requirement. The default is to produce code which does use separate vector space.</td>
</tr>
<tr>
<td><strong>W</strong></td>
<td>Enables the configurer to recognize the full range of transputer instructions, via the <code>ASM</code> construct. See section 2.10 and Appendix C in the User Guide.</td>
</tr>
<tr>
<td><strong>WALL</strong></td>
<td>Enables all warnings. See section 2.8.</td>
</tr>
<tr>
<td><strong>WD</strong></td>
<td>Provides a warning whenever a name is descoped.</td>
</tr>
<tr>
<td><strong>WO</strong></td>
<td>Provides a warning whenever a run-time alias check is generated.</td>
</tr>
<tr>
<td><strong>WQUAL</strong></td>
<td>Enables software quality warnings, see section 2.8.</td>
</tr>
<tr>
<td><strong>X</strong></td>
<td>Produces code in UNIVERSAL error mode. See section 2.4.</td>
</tr>
<tr>
<td><strong>Y</strong></td>
<td>Disables interactive debugging with <code>idebug</code>. See section 2.9.</td>
</tr>
</tbody>
</table>

Table 2.1  occonf command line options

2.2.1 Search paths

If a directory path is not specified the configurer uses the standard toolset search mechanism for locating input files, include files, and system library files. Briefly, the current directory is searched first, followed by the directories specified by `ISEARCH` (if defined on the system). For details see section A.4.

2.3 Boot-from-ROM options

The boot-from-ROM options 'RO' and 'RA' indicate that the program is to be collected for loading into EPROM and select the execution mode (from ROM or RAM) for the root transputer code. Interactive debugging must be disabled.
2.4 Configuration error modes

The configuration error mode determines the behavior of a program if it fails during execution. The execution behavior of programs configured in the different modes is as follows:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HALT</td>
<td>An error halts the transputer immediately.</td>
</tr>
<tr>
<td>STOP</td>
<td>An error stops the process and causes graceful degradation.</td>
</tr>
<tr>
<td>UNIVERSAL</td>
<td>Code configured in this mode behave as either HALT or STOP mode, according to the state of the transputer's $\text{HaltOnError}$ flag.</td>
</tr>
</tbody>
</table>

The error mode selected for the configuration must be compatible with the error mode of the compiled units, referenced by the configuration source. The configurer will produce an error message, if this is not the case.

Table 2.2 indicates the compilation error modes which are compatible and the possible error mode they may be configured for.

<table>
<thead>
<tr>
<th>Compatible compilation error modes</th>
<th>occonf options</th>
</tr>
</thead>
<tbody>
<tr>
<td>HALT, UNIVERSAL</td>
<td>H</td>
</tr>
<tr>
<td>STOP, UNIVERSAL</td>
<td>S</td>
</tr>
<tr>
<td>UNIVERSAL</td>
<td>X</td>
</tr>
</tbody>
</table>

Table 2.2 occonf error modes

Compilation error modes and their effects are described in more detail in section 5.3.1. Note: that occam UNDEFINED mode can be achieved by using the configurer 'u' option, to disable the insertion of run-time checks. This option behaves in the same way as the ‘u’ option to the occam compiler, which is documented in section 5.3.2 of the User Guide.

2.5 Enable/Disable Error Detection

By default the configurer inserts code to execute run-time checks for errors it cannot detect during configuration. In some circumstances it may be desirable to omit the run-time error checking in one part of a program, for example, in a time-critical section of code, while retaining error checks in other parts of a program, for debugging purposes. Three command line options are provided to enable the user to control the degree of run-time error detection performed; they are the ‘K’, ‘U’ and ‘NAX’ options.

The ‘K’ option disables the insertion of run-time range checks on array subscripting and array lengths.

The ‘U’ option prevents the configurer from inserting any code to explicitly perform run-time checks. This option will disable run-time checks associated with type
conversion, shift operations, array access, range validation and replicated constructs such as SEQ, PAR, IF, and ALT.

The 'NA' option prevents the configurer from inserting any code to check calls to ASSERT. In effect, each ASSERT behaves like SKIP. Any calls to ASSERT which can be evaluated during configuration will still be checked.

Note: that some checks are still performed; some transputer instructions implicitly check for erroneous conditions.

The K, U and NA options behave in exactly the same way, as the same options provided for the occam compiler. The effects of using these options are described in section 5.3.2 of the User Guide.

2.6 Enabling memory re-ordering and placement

The 'RE' option enables the user to have more control of the layout of code and data areas in memory. When this option is used, the special processor attributes 'order.code', 'order.vs' and 'order.ws' which indicate the relative priority of different data areas, and the placement attributes location.code, location.ws, and location.vs, are enabled. See sections 6.5.5 and 6.5.7 in the User Guide for more details.

Note: use of this option means that idebug cannot be used, neither in interactive mode nor in postmortem mode.

2.7 Disabling virtual routing

The virtual routing facilities of the configurer are normally enabled, that is, the configurer automatically adds virtual routing and multiplexing processes if they are required by the configuration, and any explicit placements are ignored.

If virtual routing is not required the virtual router can be disabled by using the 'NV' command line option. In the absence of explicitly supplied multiplexing processes, the normal limit of two channels per link (one in each direction) and a maximum of 4 links applies. If these limits are exceeded and no multiplexing is provided the configuration will not compile. Note: the use of the 'NV' option also has an effect on the value of LoadStart, see section 2.12.1.

Note: The 'NV' option can be used to reproduce the channel behavior of the D7205/D5205/D6205 occam 2 toolsets, if this is required.

Note: if any part of the program has been compiled with interactive debugging disabled this will also disable the use of virtual routing.

2.8 Enabling/disabling warning messages

There are several command line options which allow the user to either enable or disable the generation of certain warning messages by the configurer:
• The \texttt{NWCA} option disables the generation of warning messages when the \texttt{CHAN OF ANY} is used. \texttt{CHAN OF ANY} is now considered obsolete and replacement with named protocols of type \texttt{ANY} is recommended. See section A.2.3 of the \textit{occam 2 Toolset Language and Libraries Reference Manual}.

• The \texttt{NWGY} option disables the generation of warning messages when the \texttt{GUY} construct is used. \texttt{GUY} is now considered obsolete and \texttt{ASM} should be used instead.

• The \texttt{NWP} option disables warning messages being generated when parameters to procedures are declared and not used.

• The \texttt{NWU} option disables warning messages being generated when variables or routines are not used.

• The \texttt{WALL} option turns on all warnings i.e. it is currently equivalent to \texttt{WD}, \texttt{WO} and \texttt{WQUAL}.

• The \texttt{WD} option provides a warning whenever a name is descoped, for example when a name is used twice and one occurrence of it is hidden within an inner procedure. See section 8 of the \textit{occam 2 Reference Manual} for details of \textit{occam} scope rules.

• The \texttt{WO} option provides a warning whenever a run-time alias check is generated i.e. to check that variables do not overlap. These checks generate extra code and the user may wish to be alerted to this.

• The \texttt{WQUAL} option enables software quality warnings. Currently these include warnings for unused options in \texttt{CASE} inputs and warnings about badly positioned \texttt{PLACE} statements.

Section 2.13.1 lists the various warning messages which are affected by these options.

\section*{2.9 Support for interactive debugging}

Interactive debugging with \texttt{idebug} is supported by default. When interactive debugging is enabled the configurer will generate calls to library routines to perform channel input and output, rather than using the transputer's instructions. Interactive debugging must be enabled in order to use the interactive features of the debugger.

\textbf{Note:} when interactive debugging and virtual routing are both enabled, the direct placement of channels on inter-processor links is ignored by the configurer. See section 6.5.2 of the \textit{occam 2 Toolset User Guide} for more details.

Interactive debugging may be disabled by using the configurer \texttt{'y'} option. If this option is used in conjunction with the \texttt{'NV'} option the configurer is forced to use sequences of transputer instructions for channel input and output, resulting in faster code execution.
2.10 ASM code

Two configurer options are provided to enable the configurer to recognize transputer instructions, via the `ASM` construct (see Appendix D of the *User Guide*).

The `w` option enables the full range of transputer instructions, as listed in Appendix C of the *User Guide*. The `g` option enables the use of a limited range of sequential instructions, as listed in section C.8 of the same appendix. Examples of the use of transputer code insertion can be found in Chapter 13 of the *User Guide*.

The transputer instruction set is documented in full in the *Transputer Instruction Set – A compiler Writer’s Guide*.

2.11 Support for INQUEST

The `GA`, `PRE` and `PRU` command line options support the use of the INMOS INQUEST debugging and profiler tools.

2.12 Default memory map

By default the configurer maps code into memory into the same order as the compiler i.e. beginning at `LoadStart`: workspace; code; separate vector space. The memory segments are contiguous. The upper limit of the memory available to the configurer is defined in the configuration description file (`.pgm` file), by the `memsize` attribute specified for the processor node. The default memory map is illustrated in Figure 2.1.
The first 2 or 4 Kbytes of memory above MOSTNEG INT is implemented as on-chip RAM, and includes a few words which are reserved by the transputer hardware for the implementation of links and other hardware registers. LoadStart is either just above or coincident with MemStart, see below. Free memory is unused memory, not available to the program.

2.12.1 LoadStart

The position of LoadStart for a processor varies depending on the use of occonf command line options and the reserved processor attribute, optionally specified within a configuration description.

When the reserved processor attribute is specified, LoadStart is defined to be the memory location obtained by adding the value of reserved to MOSTNEG INT.

When the reserved processor attribute is not specified, LoadStart is coincident with or just above MemStart:

- **LoadStart** = (MOSTNEG INT + 40 words) when no command line options are used i.e. virtual routing support is enabled.
- **LoadStart** = (MemStart + 6 words) when the 'NV' command line option is specified, disabling virtual routing, but debugging or profiling is enabled either for idebug or the INQUEST product.
- **LoadStart** = MemStart when the 'NV' command line option is specified but neither idebug or the INQUEST debugger or profiler are used.

The value of LoadStart can be checked once the application has been collected, by generating and examining the collector map file.

2.13 Configurer diagnostics

If the source code does not conform to the OCCAM 2 configuration language definition, then the configurer will issue diagnostics, in the form of error messages,
during the compilation process. When this occurs no object file nor configuration binary file will be produced.

Errors in the configuration source produce diagnostic messages in standard toolset format. Details of the format can be found in section A.7.

Diagnostics are generated at the standard severity levels Information, Warning, Error, and Fatal. No messages are generated at severity level Serious.

Warning messages are listed below.

2.13.1 Warning messages

In the following list the Warning prefix is omitted for clarity.

Badly formed #PRAGMA name directive

The pragma directive named does not conform to the required syntax.

CHAN OF ANY is obsolete: use PROTOCOL name IS ANY

The CHAN OF ANY construct is now considered obsolete. The ability to define a named protocol as in PROTOCOL name IS ANY provides greater security and should be used in preference. This warning may be disabled by means of the NWCA command line switch.

GUY construct is obsolete: use ASM instead

The GUY construct is obsolete; the ASM construct provides greater security and should be used in preference. This warning message may be disabled by means of the NWGY command line switch.

Exceeded linkquota on processor name, n Inputs, n Outputs

The configurer needs to use more links than permitted by the linkquota attribute to route the channels for this program. The linkquota attribute will be ignored.

name is not used

The named variable is never used. This warning may be disabled by means of the NWU command line option.

Name name descopes a previous declaration.

This name descopes another name which has already been declared. This warning is only enabled by means of the WD command line option.

No channel has been placed onto the host connection

PLACE or MAP statements should be used to define channel input/output across the host connection, if host communication is required.
No direction known for channel *name* on PROCESSOR *name*

The configurer cannot determine whether channel *name* is used for input or output on this processor; it will make a guess.

Obsoleted channel type conversion: use channel RETYPE

The ability to pass a CHAN OF ANY as an actual parameter to a procedure whose formal parameter is a different channel type is obsolete. A channel RETYPE should be inserted before the call to make the type conversion explicit. This warning may be disabled by means of the NWCA command line switch.

Parameter *name* is not used

The named parameter is never used. This warning may be disabled by means of the NWP command line option.

Placement expression for *name* clashes with virtual routing system

The named variable is placed on one of the transputer links. This may interfere with the INMOS interactive debugging system or the virtual routing system.

Placement expression for *name* wraps around memory

The calculation of the machine address for this variable has overflowed; the truncated address is used.

Placement of *name* is ignored because interactive debugging is enabled

A channel placement on an ARC has been ignored. This is because the debugger idebug, which is enabled by default, requires all channel connections between processors to be implemented as virtual channels.

Possible side-effect: PLACED variable *name*

A PLACED variable has been declared inside a VALOF. The compiler cannot ensure that this cannot cause a side-effect.

Possible side-effect: instanced PROC has PLACED variable *name*

A PLACED variable has been declared inside a PROC which is called from within a VALOF. The compiler cannot ensure that this cannot cause a side-effect.

Processor *name* unused

The named processor has no code placed onto it.

Routine *name* is not used

The named routine is never called. This warning may be disabled by means of the NWU command line option.
Run-time disjointness check inserted

number Run-time disjointness checks inserted

The configurer has inserted run-time checks to ensure that variables are not aliased (i.e. that they do not overlap). This warning is only enabled by means of the \texttt{wo} command line option.

Unknown \#PRAGMA name: \texttt{name}

The named pragma is unknown and therefore ignored.

Using length \texttt{'name'} in array part of counted array input is obsolete

The language no longer permits using the length part of a counted array input to appear in the array part. It does however allow the following special case to be written where the length only appears as the length of a slice:

\begin{verbatim}
channel.exp \ ? \ name :: [ array.exp FROM 0 FOR name ]
\end{verbatim}

This is transformed by the compiler into the equivalent construct:

\begin{verbatim}
channel.exp \ ? \ name :: array.exp
\end{verbatim}

The former construct is obsolescent and programs should be re-written to use the latter form.

Workspace clashes with variable PLACED AT WORKSPACE \texttt{number}

A variable has been placed at the address \texttt{number} in workspace, and this clashes either with another placed variable, or with the configurer's workspace allocation requirements.

2.13.2 Error messages

Most of the messages in this section have been caused by mis-use of the configuration language. For further help see chapters 6, 10 and appendix A of the \textit{occam 2 Toolset User Guide}. These messages are generated at the severity level \textit{Error}.

\texttt{name has already been mapped}

\texttt{name} appears twice on the left-hand side of a \texttt{MAP} or \texttt{PLACE} statement.

\texttt{name has already been used as a physical NODE}

Some attributes have already been set for \texttt{name}, so it can only be used as a physical node and not as a logical node.

\texttt{ARC name has already been connected}

Examine all 'CONNECT' statements creating link connections between processor edges or a processor edge and an external edge.
Attribute name has already been set on NODE name

Check the declaration of node name and any attributes defined for name in the mapping and network sections.

Attribute name has not been set for NODE name

Attribute name is a mandatory node attribute and should be set in the NETWORK description.

Attribute name may not be SET

You may not SET a link attribute.

Attribute name may not be used on logical NODEs

Logical nodes cannot have attributes set for them. Perhaps you meant to set the attribute for a node representing a physical processor.

Attribute name set to illegal value on NODE name

Check the syntax and range of permitted values for the type of attribute required. For further help see the relevant chapters of the User Guide as indicated at the start of this section.

CHAN name is placed but not properly connected

Check that the ARC that CHAN name is PLACEd on is connected within the NETWORK description by a CONNECT statement.

CONNECT expression must be of type EDGE

CONNECT expressions connect two nodes or a node to an external edge by specifying their link connections. They take the form:

'CONNECT edge TO edge [WITH arcname]'  

where arcname is optional.

Cannot PLACE name which was declared outside a PROCESSOR construct

PLACE statement must immediately follow channel declaration.

Cannot disable interactive debugging with the INQUEST debugger

You have used both of the command line options 'x' and 'GA'; they are incompatible.

Cannot disable virtual routing with the INQUEST debugger

You have used both of the command line options 'NV' and 'GA'; they are incompatible.
2.13 Configurer diagnostics

Cannot interactively debug ROM programs

If you are configuring for boot-from-ROM i.e. you have used either the RA or RO command line options, you must disable interactive debugging by using the Y option.

If you want to debug your program, develop it as a boot-from-link program and debug, and when it is clear of errors re-configure for boot-from-ROM.

Cannot run both profilers together

You have used both the PRE and PRU command line options, selecting both INQUEST profiler tools. These tools are mutually exclusive.

Cannot run the profiler on ROM programs

The PRE or PRU command line options have been used in conjunction with the RA or RO command line options.

Cannot run the profiler with the INQUEST debugger

The PRE or PRU command line options have been used in conjunction with the GA command line option.

Cannot set NODE name as root; another has already been set

Examine the other processor declarations, one of them has the root attribute set.

Cannot use VAL on a CHAN, PORT, TIMER, or hardware item

Abbreviations of CHAN, PORT, TIMER, NODE, ARC and EDGE cannot use 'VAL'.

Cannot use VAL on a hardware item

It is illegal to use VAL on a NODE, ARC or EDGE.

Channel name is mapped onto ARC name, not connected to this processor

You need to identify which physical or logical processor is connected to ARC name. Either the ARC is connected to the wrong processor or you are trying to map the wrong channel to ARC name.

Channel name is used for both input and output, but ARC name connects to an EDGE

ARC name connects this processor to an edge, so this processor can input on it or output on it but cannot do both. Two channels are required to support two-way communication.

Channel name mapped onto unconnected ARC name

ARC name is required to be connected to a physical link. This is done using a CONNECT statement within the NETWORK description e.g.: ‘CONNECT edge TO edge [WITH arcname]’
Channel name used for input by more than one process

Channel name appears in a previous PROCESSOR statement, defining a process and its channels.

Channel name used for output by more than one process

Channel name appears in a previous PROCESSOR statement, defining a process and its channels.

Channel name with protocol containing INT used across different word-lengths

This is a constraint of the current configurer, see section A.7 of the occam 2 Toolset User Guide.

Code buffer full (nnn bytes); use command line to increase buffer size

The configurer has an internal buffer for code which is about to be placed into the object file; this has overflowed. The CODE command line option may be used to increase the size of this buffer.

EDGE name has already been connected

Edge name has been connected in a previous CONNECT statement.

EDGE name is not connected to rest of network

Edge name defines a peripheral device which, if it is to be used, needs to be connected to the rest of the network by a CONNECT statement.

Expected a NODE attribute, found a subscript expression

You appear to have used too many subscripts. The configurer expected to see the name "link" as in:

CONNECT name [link] [number] TO ........

where name is a node name and number is the link connection

FUNCTION name returns a REAL result but is compiled for wrong calling convention

A routine compiled for class TA can only be run on a T800 if it obeys the correct calling conventions. See the advice for occam code given in section B.2.3. Alternatively re-compile your code for a T8 transputer.

Illegal item in configuration code

An illegal expression has been used in the configuration description. Check the description against the syntax definition, described in appendix A of the occam 2 Toolset User Guide.
Illegal item inside CONFIG construct

Check the configuration description against the syntax definition, described in appendix A of the *occam 2 Toolset User Guide*.

Illegal item inside MAPPING construct

Check the configuration description against the syntax definition, described in appendix A of the *occam 2 Toolset User Guide*.

Illegal item inside NETWORK construct

Check the configuration description against the syntax definition, described in appendix A of the *occam 2 Toolset User Guide*.

Illegal processor type "name"

Supported processor types are: "T212" "T222" "T225" "M212" "T400" "T414" "T425" "T800" "T801" "T805"

Implementation restriction: Cannot RETYPE INT constants on 16-bit processors; use INT16

This is a constraint of the current configurer, see section A.7 of the *occam 2 Toolset User Guide*.

Implementation restriction: Cannot declare *name* inside a replicator

Declarations of NODES, ARCS, and EDGES may not appear inside a replicator.

Implementation restriction: Cannot use INT constant arrays on 16-bit processors; use INT16

This is a constraint of the current configurer, see section A.7 of the *occam 2 Toolset User Guide*.

Implementation restriction: Cannot use replicator *name* in channel abbreviation outside a PROCESSOR construct

You have encountered an implementation restriction.

Implementation restriction: INT constant overflows on 16-bit processors; use INT16

This is a constraint of the current configurer, see section A.7 of the *occam 2 Toolset User Guide*.

Implementation restriction: root NODE *name* must not be an array element

You have encountered an implementation restriction.
Left hand side of mapping must be of type CHAN

Channels are mapped onto an ARC, with a statement of the following form:

\texttt{MAP channel.list ONTO arc}

where \texttt{channel.list} is a list of channels previously declared to have type CHAN.

Left hand side of mapping must be of type NODE

Logical processors are mapped onto a physical processor, with a statement of the following form:

\texttt{MAP processor.list ONTO node}

where \texttt{processor.list} is a list of logical processors previously declared as NODE types.

Link \texttt{name[link][number]} has already been connected

Check any previous CONNECT statements to identify what link \texttt{name[link][number]} is connected to.

Link number \texttt{number} is illegal for this NODE

T400 and M212 transputers have just two links, identified 0 and 1. All other transputers in the current range have four links, numbered 0, 1, 2 and 3.

Location attributes ignored because re-ordering isn't enabled

Use the \texttt{RE} command line option to enable the \texttt{location} attributes.

Multiple CONFIG constructs not permitted

The CONFIG keyword introduces the software description, which is a PAR or PLACED PAR and should include PROCESSOR statements defining all required software processes.

Multiple MAPPING constructs not permitted

All MAP statements should appear in one section introduced by the MAPPING keyword. Any attributes used to control the use of memory or routing should also be included in this section.

Multiple NETWORK constructs not permitted

All statements describing the connectivity and attributes of physical nodes should be placed in one section, introduced by the NETWORK keyword.

\texttt{NODE name} has not been mapped

Check your mapping description, a logical processor has been declared but not mapped to a physical processor.
No CONFIG construct

The software description is missing or has not been introduced by a CONFIG keyword.

No NETWORK construct

The network description is missing or has not been introduced by a NETWORK keyword.

No NODE has been specified as root

Configurations which are for boot-from-ROM application must have one physical node defined to be the root transputer. This is performed using the root attribute in a SET statement.

No hardware route exists from processor name for channel name

There is no direct link available for channel name to use. Because through-routing has been disabled by the nv command line option an indirect route cannot be established.

No priority expression permitted when mapping CHANs

The priority expression PRI can only be used when mapping logical processors onto physical processors. The priority expression relates to the software process which will run on the processor.

Not enough links from processor name for channel name

The nv command line option has been specified, disabling virtual routing. This means that only one channel can be placed in each direction, onto each link specified in the hardware description.

Ordering attributes ignored because re-ordering isn’t enabled

Use the RE command line option to enable the order attributes.

PRI expression nn must evaluate to 0 or 1

Priority expressions are introduced by a PRI keyword in a MAP statement. PRI expressions may take one of two integer values; either 0 indicating high priority or 1 indicating low priority.

Priority expression of mapping must be of type INT

PRI expressions may take one of two integer values; either 0 indicating high priority or 1 indicating low priority.

Process evaluates to STOP

The logic within the configuration description itself evaluates to a STOP and will therefore not execute.
Process mapped at high priority may not contain a PRI PAR

The logic of the MAP statement which includes the PRI expression conflicts with the internal logic of the program which uses a PRI PAR.

Processor type has already been set for NODE name

Node name already has the type attribute set. Check the hardware description.

Processor type has not been set for NODE name

The attribute type is a mandatory node attribute and should be set in the hardware description for NODE name.

ROM memory size has not been set for root NODE

The size of ROM attached to the root node must be specified using the romsize attribute. (The root node is the node which has the root attribute set).

Right hand side of mapping must be a physical NODE

Logical processors are mapped onto a physical processor, with a statement of the following form:

MAP processor.list ONTO node

where node is a physical node declared within the hardware description.

Right hand side of mapping must be of type ARC

Channels are mapped onto an ARC, with a statement of the following form:

MAP channel.list ONTO arc

where arc is a named link declared within the hardware description.

Right hand side of mapping must be of type NODE or ARC

MAP statements are used to map logical processors onto physical processors or channels onto named links called ARCs. The statement takes the form:

MAP processor.list ONTO node

where node is a physical node declared within the hardware description.

OR:

MAP channel.list ONTO arc

where arc is a named link declared within the hardware description.
SET expression must be of type NODE

The SET expression is used to set attributes for physical processors. It takes the form:

\textit{SET device (attribute.assignment)}

where \textit{device} is a node name.

Too many channels inputting on ARC \textit{name}

An ARC can carry a maximum of two channels, one in either direction. It is a dedicated link \textit{i.e.} one which will not be used by virtual channels.

Too many channels outputting on ARC \textit{name}

An ARC can carry a maximum of two channels, one in either direction. It is a dedicated link \textit{i.e.} one which will not be used by virtual channels.

Unknown attribute name \textit{name}

The attribute \textit{name} used is not supported by the language. Valid attributes are:

\textit{link linkquota location.code location.ws location.vs memsize nodebug noprofile order.code order.ws order.vs reserved romsize root routecost tolerance type}

Further information can be found in appendix A of the \textit{occam 2 Toolset User Guide}.

Value must be in range 0 to \textit{n} for attribute \textit{name}

Attribute \textit{name} has been incorrectly specified.

WITH expression must be of type ARC

The only configuration statement that a WITH expression may appear in, is a CONNECT statement. This is used to connect an ARC with a link connection. It takes the form:

`CONNECT edge TO edge [WITH arcname]`
This chapter describes the code collector tool *icollect* which generates an executable file for a single or multitransputer program from a configuration data file, or for a single transputer program directly from a linked unit. The tool is also used to create files for input to the EPROM programmer tool *ieprom*, and to create files that can be dynamically loaded by a user program.

### 3.1 Introduction

*icollect* generates bootable files for transputer programs, and other executable files in special formats.

Bootable files are transputer executable files that can be directly loaded onto the transputer hardware down a transputer link. The bootable file contains all the information for loading and running the program on a specific network of processors, including data that controls the distribution of code on the network, and self-booting code for each processor. Bootable programs are therefore self-distributing and self-starting when they are sent down a transputer link.

Recommended program development for single and multitransputer programs is to create a configuration data file (i.e. binary file) and to use this as input to the collector. The configuration data file describes the placement of processes and channels on the processor network in a special format which can be read by the collector. They are created from configuration descriptions by the configurer.

Single transputer programs can by-pass the configuration stage and use a single linked unit as input. The collector then adds bootstrap and system code for a single processor. Unconfigured programs can only run on a single transputer. This method of program development is not recommended and may not be supported in future toolsets.

*icollect* can be directed to generate output files in a special format for processing by the *ieprom* tool, and executable code with no bootstrap or system process information, intended for dynamic loading by a supervisory program.

The command line default is to assume input from a configuration binary file. Special format outputs are selected by specifying command line options.

The main inputs and outputs of the collector tool for bootable programs are shown below.
3.2 Running the code collector

The code collector is invoked using the following command line:

```plaintext
icollect filename {options}
```

where: `filename` is a configuration data file created by a configurer or a single linked unit created by `ilink`. Only one filename may be given on the command line.

`options` is a list of the options given in Table 3.1.

```
| Options must be preceded by '-' for UNIX-based toolsets and '/' for MS-DOS and VMS based toolsets. |
| Options may be entered in upper or lower case and can be given in any order. |
| Options must be separated by spaces. |
```

If no arguments are given on the command line a help page is displayed giving the command syntax.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B <strong>filename</strong></td>
<td>Uses a user-defined bootstrap loader program in place of the standard bootstrap. The program is specified by <strong>filename</strong> and must conform to the rules described in appendix E. This option can only be used with the 'T' option (unconfigured mode) and cannot be used with the 'RA' and 'RO' options.</td>
</tr>
<tr>
<td>BM</td>
<td>Instructs the tool to use a different bootstrapping scheme, which uses the bottom of memory, see section 3.9. This option is only valid for configured programs i.e. when the 'T' option is not used.</td>
</tr>
<tr>
<td>C <strong>filename</strong></td>
<td>Specifies a name for the debug data file. A filename must be supplied and is used as given. This option can only be used with the 'T' option (unconfigured mode) and cannot be used with the 'D' or 'K' options.</td>
</tr>
<tr>
<td>CM</td>
<td>Instructs the collector to add a bootstrap which will clear memory during the booting and loading of the transputer network. Intended for use with parity-checked memory (see section 3.5).</td>
</tr>
<tr>
<td>D</td>
<td>Disables the generation of the debug data file for single transputer programs. This option can only be used with the 'T' option (unconfigured mode).</td>
</tr>
<tr>
<td>E</td>
<td>Changes the setting of the transputer Halt On Error flag. HALT mode programs are converted so that they not stop when the error flag is set, and non HALT mode programs to stop when the error flag is set. This option can only be used with the 'T' option (unconfigured mode).</td>
</tr>
<tr>
<td>I</td>
<td>Displays progress information as the collector runs.</td>
</tr>
<tr>
<td>K</td>
<td>Creates a single transputer file with no bootstrap code. If no file is specified the output file is named after the input filename and given the .rsc extension. This option can only be used with the 'T' option (unconfigured mode).</td>
</tr>
<tr>
<td>M <strong>memorysize</strong></td>
<td>Specifies the memory size available (in bytes) on the root processor for single transputer programs. <strong>memorysize</strong> is specified in bytes and may be given in decimal format (optionally followed by 'K' or 'M' to indicate Kilobytes or Megabytes respectively), or it may be specified in hexadecimal using the '#1 or '$ prefixes. This option can only be used with the 'T' option (unconfigured mode) and results in a smaller amount of code being produced (see section 3.4).</td>
</tr>
</tbody>
</table>
### 3.2 Running the code collector

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>O</strong> <em>filename</em></td>
<td>Specifies the output file. A filename must be supplied and is used as given. (See section 3.2.4).</td>
</tr>
<tr>
<td><strong>P</strong> <em>filename</em></td>
<td>Specifies a name for the memory map file. A filename must be supplied and is used as given. The file extension <code>.map</code> should be used when the file is to be used as input to <code>imap</code>, see chapter 12.</td>
</tr>
<tr>
<td><strong>RA</strong></td>
<td>Creates a file for processing by <code>ieprom</code> into a boot from ROM file to run in RAM. If no output file is specified the filename is taken from the input file and given the <code>.btr</code> extension. This option is only necessary when using the <code>'T'</code> option (unconfigured mode) to create a ROM code file.</td>
</tr>
<tr>
<td><strong>RO</strong></td>
<td>Creates a file for processing by <code>ieprom</code> into a boot from ROM file to run in ROM. If no output file is specified the filename is taken from the input file and given the <code>.btr</code> extension. This option is only necessary when using the <code>'T'</code> option (unconfigured mode) to create a ROM code file.</td>
</tr>
<tr>
<td><strong>RS</strong> <em>romsize</em></td>
<td>Specifies the size of ROM on the root processor in bytes. Only valid when used with the <code>'RA'</code> or <code>'RO'</code> options. <code>romsize</code> is specified in bytes and may be given in decimal format (optionally followed by <code>'K'</code> or <code>'M'</code> to indicate Kilobytes or Megabytes respectively), or it may be specified in hexadecimal using the <code>'#'</code> or <code>$</code> prefixes. This option is only necessary when using the <code>'T'</code> option (unconfigured mode) to create a ROM code file.</td>
</tr>
<tr>
<td><strong>S</strong> <em>stacksize</em></td>
<td>Specifies the extra runtime stack size in words for single transputer programs. (For occam programs this option refers to <code>stack.buffer</code>, see section 3.4.2 for details). <code>stacksize</code> is specified in words and may be given in decimal format (optionally followed by <code>'K'</code> or <code>'M'</code> to indicate Kilowords or Megawords respectively), or it may be specified in hexadecimal using the <code>'#'</code> or <code>$</code> prefixes. This option can only be used with the <code>'T'</code> option.</td>
</tr>
<tr>
<td><strong>T</strong></td>
<td>Creates a bootable file for a single transputer. The input file specified on the command line must be a linked unit. This option can not be used for C programs which are linked with the reduced runtime library.</td>
</tr>
<tr>
<td><strong>Y</strong></td>
<td>Disables interactive debugging with <code>idebug</code> and reduces the amount of memory used. (See section 3.11). This option can only be used with the <code>'T'</code> option (unconfigured mode).</td>
</tr>
</tbody>
</table>

Table 3.1  *icollect* command line options
3.2.1 Examples of use

Example A (unconfigured program mode):

UNIX based toolsets:

```
icc hello
ilink hello.tco -f cnonconf.lnk
icollect hello.lku -t
iserver -sb hello.btl -se
```

MS-DOS/VMS based toolsets:

```
icc hello
ilink hello.tco /f cnonconf.lnk
icollect hello.lku /t
iserver /sb hello.btl /se
```

Example B (configured program mode):

UNIX based toolsets:

```
icc hello
ilink hello.tco -f cstartup.lnk
icconf hello.cfs
icollect hello.cfb
iserver -sb hello.btl -se
```

MS-DOS/VMS based toolsets:

```
icc hello
ilink hello.tco /f cstartup.lnk
icconf hello.cfs
icollect hello.cfb
iserver /sb hello.btl /se
```

Note: single transputer programs linked with the reduced runtime libraries cannot be linked and collected with the 'T' option, they must be configured.

3.2.2 Default command line

Commonly used command line parameters can be defined for the tool using the ICOLLECTARG environment variable. Parameters specified in this way are automatically added to the command line when the tool is run.

Parameters in ICOLLECTARG must be specified using the syntax required by the command line.

3.2.3 Input files

The input file to icollect is either a configuration data file generated by a configurer, or a linked unit generated by ilink. By default the collector assumes a configuration data file; for single transputer programs the input file may be a linked unit, in this case the 'T' option must be given.

Input files of an incorrect format generate an error message and no output is produced.

3.2.4 Output files

The output produced by the tool depends the type of file input to the collector and the collector options used.
3.3 Program interface for occam unconfigured programs

Specifying an output filename

An output filename can optionally be specified using the \( O \) option, followed by a filename, which will be used as given. If the \( O \) option is not used, the input filename will be used with an extension added indicating the file type, see below.

Default case

The default output file is a binary file that can be loaded directly onto the transputer hardware down a transputer link. This type of file is known as a boot from link program. By default the file is given the .btl extension.

Boot-from-ROM/RAM

Boot-from-ROM programs output is generated by using the appropriate command line options; \( RO \) for boot-from-ROM; \( RA \) for boot-from-RAM. By default the file will be given the .btr extension.

C and FORTRAN programs must be configured, prior to using icollect, in order to generate boot-from-ROM or RAM output. occam boot-from-ROM or RAM output can be generated from either configured or unconfigured input.

Dynamically loadable output

Dynamically loadable code is generated by using the \( K \) command line option. By default the file is given the .rsc extension.

Dynamically loadable code file may only be generated when the input to the collector is a linked unit and the \( T \) option is used, i.e. this type of output can only be produced for the unconfigured case.

Memory map files

A memory map file may be generated, in addition to the normal output, by specifying the ‘P’ option. The format of these files is described in section 3.10.

Debug data file

For unconfigured transputer programs only, the collector automatically generates a configuration binary file for use by the debugger. By default the filename stem is taken from the output file and the extension ‘.cfb’ is added. If the ‘C’ option is specified then the filename given is used, as supplied. Generation of the debug data file can be disabled with the ‘D’ option.

3.3 Program interface for occam unconfigured programs

For programs which are loaded onto a single transputer, the program interface must conform to the appropriate format, depending on whether or not memory size is specified on the collector command line.
3.3.1 Interface used for 'T' option

OcCAm programs which are collected with the T option, without specifying memorysize (using the M option), must use one of the following formats of procedure declaration:

\[
\begin{align*}
\text{PROC program} & \quad (\text{CHAN OF SP from.link, to.link,} \\
& \quad [\text{INT user.buffer}]) \\
\text{PROC program} & \quad (\text{CHAN OF SP from.link, to.link,} \\
& \quad [\text{INT user.buffer, stack.buffer}])
\end{align*}
\]

where: from.link and to.link are the input and output channels respectively of the transputer link, down which the transputer was booted.

user.buffer is the free memory buffer.

stack.buffer is a buffer allocated at the base of memory by the collector, whose size is determined by the S option. If the S option is not specified when icollect is invoked this buffer will be of size zero.

3.3.2 Interface used for 'T' and 'M' options

In the case where both the 'T' and 'M' options are used, the program must conform to one of the following procedure declarations:

\[
\begin{align*}
\text{PROC program} & \quad (\text{CHAN OF any protocol from.link, to.link,} \\
& \quad [\text{INT user.buffer}]) \\
\text{PROC program} & \quad (\text{CHAN OF any protocol from.link, to.link,} \\
& \quad [\text{INT user.buffer, stack.buffer}])
\end{align*}
\]

where: The channel protocol can take any valid type.

The other variables are as defined above.

3.4 Memory allocation for unconfigured programs

The memory allocation outlined in this section applies only to single processor programs collected with the 'T' option and without the 'K' option. For configured programs the layout of code and data in memory is determined by the configurer. For programs generated with the 'T' option the layout is determined by the collector. The details of memory use depend on the language used and the options to icollect, this is described below.

Memory which is not reserved by the system for program code and data (known as free memory) can be made available to a user application. For C programs this is used for the heap and, optionally, the stack. In the case of a single transputer OcCAm program the free memory passed as an array.

To calculate the actual memory available, the loader program in the bootable file first reads the total memory size from the host environment variable IBOARDSIZE.
This communication with the host is performed after the program has been loaded onto the transputer board but before the program is started. The size of the free memory is given by $\text{IBOARDSIZE}$ minus the combined program code and data space required.

The process code which reads $\text{IBOARDSIZE}$ requires approximately 3.5 Kbytes of memory. This process is executed and terminated before the user program runs, and the segment of free memory that the process uses is then returned to the user program. Therefore when the user program executes it will not know whether the process was present or not.

When the 'M' option is used to specify the memory size, $\text{IBOARDSIZE}$ is not read and therefore the total amount of memory required when loading the program will be approximately 3.5 Kbytes less.

A memory map file may be obtained by specifying the 'P' command line option. The content of memory map files is described in section 3.10.

### 3.4.1 C and FORTRAN programs

For C programs the bootstrap loader must allocate memory for static data, stack and heap areas. FORTRAN programs have similar requirements and are handled in the same way.

When the collector 'S' option is specified the program's stack is placed at the bottom of memory. When the 'S' option is not specified a stack area is allocated by the runtime system, typically at the top of free memory.

Areas for static data and heap are always allocated by the language's runtime system at the bottom of free memory. The heap area grows upwards, towards the top of memory, and the stack grows downwards.

Figure 3.1 shows the memory map layouts for programs with and without the stack requirement specified by the user.

The value of LoadStart is described in section 3.10.
3.4.2 occam programs

Figure 3.1 Memory maps for C and FORTRAN

Figure 3.2 Memory map for occam program
An occam program requires space to be allocated for code, workspace and, possibly, vector space. Programs can also be passed one or two arrays as parameters; one (always available) provides access to the free memory. The other is optional but, if used, it is placed at the bottom of the memory map to provide access to the transputer's fast internal RAM. This array is known as the stack.buffer. The default bootstrap loader attempts to optimize placement of the program's, and its own, code and workspace. If present, the stack.buffer array is placed at the bottom of memory (at LoadStart). This is followed in order by the workspace, code, vector space (if used) and free memory. The 'S' option allows space to be reserved in the internal RAM.

Figure 3.2 shows the memory map of the loaded occam code as created by the default bootstrap loader.

3.4.3 Memory initialization errors

While the loader is executing the memory initialization process, described above, warning messages may be obtained which have the following format:

Warning-SystemA- message

where: message can be one of the following:

IBOARD SIZE, unable to read

IBOARD SIZE environment variable is not defined correctly.

number, illegal format number

The value specified for IBOARDSIZE is in the wrong format.

illegal 16 bit memory size, set to zero

The value of IBOARDSIZE is greater than 64K when a 16 bit processor is being used. The memory size has therefore been set to zero.

negative memory size, set to zero

A negative value was specified for IBOARDSIZE, which has been set to zero.

unable to reset free memory

The loader cannot return the memory it has used to the user.

All the above errors are generated by the system process at runtime.

3.4.4 Small values of IBOARDSIZE

When the 't' option is used, very small values of IBOARDSIZE (including zero) are detected at runtime and prevent the program from being run. IBOARDSIZE is read
at runtime, not by the collector at build time. Small values of IBOARDSIZE cause
the collector to generate a warning message but do not prevent the generation of
a bootable file.

IBOARDSIZE must be $\geq$ to the total memory requirements of the user program
being executed.

3.5 Parity-checked memory

If any processors in the network use parity-checking on external memory (typically
using the T426) then it is essential that that memory is initialized (written to) before
it is read. Reading from an un-initialized location is likely to cause a parity error.
Internal memory is not parity-checked, so a bootstrap program can always get
started, but the initialization must be done before any program using external
memory is run. Therefore the initialization of memory must be done during the
booting and loading of the processors.

There is an option to the collector, ‘CM’, which instructs the collector to use a boot­
strap that clears memory on each transputer before the application code is
executed. This must always be used when collecting programs for a network that
contains one or more T426s. When selected, the ‘CM’ option applies to all proces­
sors in the network, not just to T426s.

In order to clear the memory on a processor, it is necessary for the bootstrapping
sequence to know the size of the memory. There are four cases to consider:

1 A configured program.

Here the memory size is known at configuration time, and is specified by
the user in the configuration source file. The bootstrapping sequence
produced by the collector will clear the amount of memory specified (in the
configuration source file) before booting the application.

2 A collected program with fixed memory size.

The collector may be used, with the ‘T’ option, to produce a bootable file
from a single linked unit. The amount of memory on the processor may be
specified with the ‘M’ option. In this case the bootstrapping sequence will
clear the amount of memory specified (with the ‘M’ option) before booting
the application.

3 A collected program with variable memory size, booted from link.

If the collector is run with the ‘T’ option, but without the ‘M’ option, the
memory size is known only at runtime. The memory size is found out at
runtime using the environment variable IBOARDSIZE. In this case the
bootstrapping sequence will clear memory up to the minimum required to
boot the program. After booting, the value of IBOARDSIZE will be read and
the remaining memory will be cleared.
4 A collected program with variable memory size, booted from ROM.

If the collector is run with the 'T' option, but without the 'M' option, and the program is booted from ROM, then the memory size is not known at all. In this case the bootstrapping sequence will clear enough memory for the minimal requirements of the application. It is then the user program's responsibility to clear any additional memory required.

Initialization of memory is carried out regardless of the processor type; memory is initialized even if the processor is not a T426. So if the 'CM' option is selected every processor's memory in the network will be initialized (including 16-bit transputers). In the case of the T426, the bootstrap code also clears the parity registers by reading them before the program starts.

3.6 Non-bootable files created with the K option

Files created with the 'K' option are non-bootable files which can be dynamically loaded or manipulated by a program at runtime. Non-bootable files cannot be loaded and run on transputer hardware in the normal way.

3.6.1 File format

Non-bootable files consist of program code preceded by a specific sequence of data words which provide runtime information. The sequence of data words and code blocks is summarized in table 3.2. Descriptions of the more important data items are given in table 3.3.

<table>
<thead>
<tr>

<td>T425, T400, T426</td>
</tr>
<tr>
<td>10</td>
<td>TA</td>
</tr>
<tr>
<td>11</td>
<td>TB</td>
</tr>
</tbody>
</table>

Version The format version number of the file. This can be either 10 or 11 in TCOFF files. For C and FORTRAN programs this value is 11, which indicates that the 'Static size' parameter (below) is present. For occam programs the value is 10, indicating no static data; the parameter list will also not be present.

Scalar workspace Specifies the size of the workspace required for the linked program's runtime stack.

Vector workspace Specifies the size of the workspace required for the linked program's vector (array) data.

Static size Specifies the size of the static area (only present if the file format version number is 11).

Entry point offset Indicates the offset in bytes of the program entry point from the base of the code block.

Code size Indicates the size of the program code in bytes.

Code The program code.

Table 3.3 Details of code segments in non-bootable files

3.7 Boot-from-ROM output files

Boot-from-ROM output files are either generated by using the collector options 'RA' or 'RO' for unconfigured programs or by configuring a program to boot from ROM, prior to collecting. (The configurer also has 'RA' and 'RO' command line options).

The boot-from-ROM files contain code that can be loaded into EPROM using the ieprom tool. The code may be run on the root transputer of a network; processors on the network connected to the root transputer are booted from the root transputer's links.

'RA' generates code which is executed from RAM. The code is copied from ROM into RAM at runtime. 'RO' generates code which is directly executed from ROM.

RAM executable code can be used for applications which are to be executed from fast RAM, and for code which may be user-modified. ROM executable code may
require no external RAM for programs which use small amounts of data and can be used to create a truly embedded system.

3.8 Alternative bootstrap loaders for unconfigured programs

If not otherwise specified, \texttt{icollect} uses the standard INMOS primary bootstrap loading sequence. The correct code for the application program is chosen automatically from a library of bootstraps compiled for different transputer types and error modes.

The collector can be directed to use other bootstrap loader programs defining different loading sequences by specifying the \texttt{B} option. This option directs the collector to append a user-defined loader program in place of the standard bootstrap code.

User-defined bootstraps must comply with the format used by the standard INMOS loader. The source of the standard INMOS Network Loader is supplied with the toolset. The source is fully commented and can be used as a template to design and code your own loading sequence.

3.9 Alternative bootstrap schemes

When building for a configured network, the collector uses a bootstrapping scheme which makes use of the top two hundred bytes of memory. This memory is required to load the last few bytes of application code prior to its execution. The memory region becomes available to the user once their application is running.

This scheme does not remove memory from the user's environment on a permanent basis and it facilitates the absolute placement of code and data by the user. See the \textit{User Guide} for details.

The user can tell the collector to use a different booting scheme by using the option \texttt{BM}. In this case the booting scheme permanently removes a section of memory from the user's environment and moves the value of \texttt{LoadStart} accordingly. This section of memory is never made available to the user. This booting scheme does not support the absolute placement of code and data by the user.

The booting scheme invoked by the \texttt{BM} option, is used by default for unconfigured programs i.e. those collected using the \texttt{T} option.

3.10 The memory map file

A memory map file may be obtained by specifying the \texttt{p} command line option, followed by a filename. Such files contain the memory layout for each processor in the network.

The file layout takes the form of a list of code and data to be placed on respective processors. The right hand side of the file gives the start and end address followed by the size of each block.
The memory map file contains the following information:

- **icollect** version data
- For each processor the following details are given:
  - Processor type
  - Error mode (HALT or STOP)
  - **LoadStart** (lowest user memory address)
  - For each process on this processor the following is listed:
    - Code, name of file, offset from start (decimal), start address and end address (hex), size (decimal), entry address (if any, in Hex)
    - Workspace, start and end address (hex), size (decimal)
    - Any other data requirements
- Boot path for the network - only present if program is configured
- Connectivity of the network - only present if program is configured

The absolute addresses are calculated using **LoadStart**, which is the base of user memory. This varies for different processor types i.e. the value of LoadStart for a T4 processor is different to that for a T8.

If the 'BM' option is used the memory from **MemStart** to **LoadStart** is used by the low level bootstraps and their workspace.

When the 'BM' option is not used the value of **LoadStart** is determined by the configuration, see the reference chapter for the configurer, for further details.

The addresses allocated to various data items reflect the command line options specified to the collector. Details of the memory map files for the following types of files are given below:

- Unconfigured (single processor), boot from link programs targetted at a specific processor type.
- Unconfigured (single processor), boot from link programs targetted at a processor class.
- Configured, boot from link programs.
- Boot from ROM (single and configured)

The examples below demonstrate the map file format; they may change in detail.

3.10.1 Unconfigured (single processor), boot from link

Program targetted at transputer type

The first memory map described in this section is for a program which is to be booted for a specific processor type.
The example shown in Figure 3.3 was produced by the following command line:

```plaintext
icollect -t hello.lku -s 400 -p hello.map (UNIX)
icollect /t hello.lku /p /s 400 hello.map (MS-DOS/VMS)
```

where: `hello.lku` was produced by compiling and linking the example program `hello.c` for a T425 in the default halt-on-error mode. The compiled object file was linked with the C linker indirect file `cnonconf.lnk` because the example is for an unconfigured program.

`hello.map` lists code and data segments to be placed on each processor (one in this case). For each process the workspace and vector space requirements are given together with the entry point of the process. Note that the first three processes listed are non-user processes; this will always be the case for this type of program.

<table>

</tbody>
</table>

Figure 3.3 Memory map file for a single T425 processor program

Program targetted at transputer class

The second memory map described in this section is for a program which is to be booted for processor classes TA or TB.
The example shown in Figure 3.4 was produced by the following command line:

```
icollect -t hello.lku -p hello.map  (UNIX)
icollect /t hello.lku /p hello.map   (MS-DOS/VMS)
```

where: `hello.lku` was produced by compiling and linking the example program `hello.c` for class TA in the default halt-on-error mode. The compiled object file was linked with the C linker indirect file `cnonconf.lnk` because the example is for an unconfigured program.

```

Figure 3.4  Memory map file for a single TA processor program
```

The memory layout of user's code and data is the same as for the previous example, except that no space is allocated for the extra stack (because extra stack was not requested on the command line). `LoadStart`, from which the start and end addresses are calculated, can only be calculated at runtime. This is because the value of `MemStart` cannot be determined at collect time. The numbers given, in place of absolute addresses are offsets from `LoadStart`.

Figure 3.5 Memory map file for a configured T425 processor program

The example shown in Figure 3.5 was produced by the following command line:

```
icollect hello.cfb -p hello.map     (UNIX)
icollect hello.cfb /p hello.map      (MS-DOS/VMS)
```

where: `hello.cfb` is the configuration binary file produced by the configurer for
the single processor 'Hello World' example program introduced in the ANSI/C Toolset User Guide.

The Memory map for the configured program is similar to that produced for unconfigured transputer programs except that it has two additional configuration sections at the end of the file. The **Boot path** for the network lists processors in the order in which they are to be booted. The **Connectivity for network** lists the link connections between the processors.

72 TDS 367 01 March 1993
3.10.3 Boot from ROM programs

There are four cases for this type of program:

- Unconfigured (single processor), boot from ROM, run in RAM
- Unconfigured (single processor), boot from ROM, run in ROM
- Configured program, boot from ROM, run in RAM
- Configured program, boot from ROM, run in ROM

The memory maps for each of these are summarized below.

Unconfigured (single processor), boot from ROM, run in RAM

The memory map for this case will have the same layout as the single processor boot from link programs.

Unconfigured (single processor), boot from ROM, run in ROM

It is not known at collect time where in memory the ROM is to be placed. Therefore, the start and end addresses of the code segments are given as offsets from the start of ROM, and are annotated as such. Items such as workspace will have absolute addresses allocated, if the program is targeted at a specific processor type.

Note: for C programs the runtime startup system would require modification first, in order to provide the system with details of heap and stack etc.

Configured program, boot from ROM, run in RAM

The layout of the memory map for this case will be the same as that for the boot from link configured program. This is because everything (code and data) is copied into RAM.

Configured program, boot from ROM, run in ROM

For this case the root processor will be shown in the same format as the single processor case, run in ROM; some memory locations being expressed as offsets from the beginning of ROM.

The other processors in the network will appear as in the boot from link case.

The example shown in Figure 3.6 was produced by the following command line:

```
icollect hello.cfb -p hello.map  (UNIX)
icollect hello.cfb /p hello.map   (MS-DOS/VMS)
```

where: hello.cfb is the configuration binary file produced by the configurer, for the single processor 'Hello World' example program introduced in the ANSI C Toolset User Guide. The configurer 'RO', 'RS' and 'P' options were used to create a boot from ROM input file for the collector.
3.11 Disabling interactive debugging – ‘Y’ option

The ‘Y’ collector option has two effects on the program being built:

- It disables interactive (breakpoint) debugging of the program
- It reduces the amount of memory used.

For programs compiled and linked for a specific transputer type, this option will cause icollect to produce a program that uses less memory. However, programs compiled and linked for transputer classes ‘TA’ or ‘TB’ will not build when this option is used. This option is only valid for programs collected with the T option.
3.12 Error messages

This section lists error messages generated by icollect. The messages are listed in alphabetical order under the appropriate severity classification. In all cases the introductory string (severity, and filename if appropriate) is omitted.

icollect generates errors of severities Warning and Serious. Serious errors cause the tool to terminate without producing any output.

3.12.1 Warnings

The following messages are prefixed with 'Warning-'. They are only generated when the 'T' option is used (single processor mode).

Extra disable option on command line ignored
The program has been configured with interactive debugging disabled and the 'y' option specified to the collector is therefore superfluous.

Flip error mode ignored with user bootstrap
The 'z' option is ignored when a user-defined bootstrap is specified since the collector will only accept a single linked unit as a bootstrap.

Program configured with interactive debugging enabled, option ignored
The program has been configured with interactive debugging enabled and the 'y' option has been specified to the collector. The 'y' option is ignored and the boot file is built.

Strange board size for sixteen bit processor: Setting to zero
The memory size specified exceeds the addressing capacity of a 16 bit processor (64 Kbytes). The collector uses a memory size of zero for the rest of the build.

3.12.2 Serious errors

The following errors are prefixed with 'Serious-'.

Address space for target processor exhausted
The address space required by the program is greater than 64Kbytes, the maximum addressable space on a 16-bit processor.

Bootstrap file already specified
More than one bootstrap file was specified. Only one file is allowed.

Bootstrap filename too long
The maximum length allowed for the bootstrap filename is 255 characters.
Bootstrap is greater than 255 byte in library file

The library bootstrap is too large. This should only occur if the library file is invalid or corrupt.

Cannot have both rom types

'RA' and 'RO' options are mutually exclusive and cannot both be specified on the same command line.

Cannot have configured and memory size

The memory size option is incompatible with building a bootable program for a configuration binary file.

Cannot have configured and non bootable file

The collector cannot generate both a network loadable file and a non-bootable file simultaneously for the same program.

Cannot have rom and non bootable file

The collector cannot generate both a ROM-loadable file and a non-bootable file simultaneously for the same program.

Cannot open file filename

Host file system error. The file specified cannot be opened.

Cannot patch parameter data for processor class

The 'y' option has been specified with a linked unit for a processor class. The collector cannot initialize some of the data without a linked unit for a specific processor type.

Cannot use absolute placement and bottom of memory loader

The user has specified BM to the collector but is using absolute code and data placement at configuration. This combination is not legal.

Command line parsing error at string

Unrecognized command line option.

Debug file already specified

More than one debug was file specified. Specify one only.

Dynamic memory allocation failure

Memory allocation error. The collector cannot allocate the required amount of memory for its internal data structures.

Error in writing to debug file

Host file system error. The debug file could not be written. This message will only appear if the collector is invoked with the 'T' option (unconfigured mode).
Expected end tag found not present in .cfb file

A specific end tag is missing in the configuration binary file. Either the file is corrupted or the versions of icollect and configurer used are incompatible.

Illegal tag found in .cfb file

Incorrect format configuration binary file, recognized as an illegal tag. Either the file is corrupted or the versions of icollect and configurer used are incompatible.

Illegal language type found in input file

Source language used to create the file is not supported by the collector. Less likely, but possible, is that the file was created using an incompatible (possibly earlier) version of a tool.

Illegal process type

Unrecognized process type. Either the file has been corrupted or the versions of icollect and configurer used are incompatible.

Illegal processor type

Unrecognized processor type. Either the file has been corrupted or icollect and the configurer are incompatible.

Illegal tag found in input file: filename

Incorrect format input file. The most likely reason for this error is that an incorrect file has been specified. Other less likely but possible explanations are that the file was created using an earlier or incompatible version of one of the tools, or that the file has become corrupted.

Input file already specified

More than one input file specified on the command line.

Input file has not been linked filename

The collector accepts only linked files, either directly when using single processor operation, or indirectly via entries in the configuration binary file. This message can be generated if the file was created using a previous version of a tool, or if the file is corrupt.

Input file is of incorrect type: filename

If the 'i' option is specified (single processor program) the input file must be a single linked unit (.lk type). If the 'i' option has not been specified the input file must be a configuration binary file (.cfb type).

Input filename too long

The maximum length allowed for the input filename is 256 characters.
Linked unit file in cfb and linked unit in input file found do not match: *filename*

The linked file specified in the configuration binary and the one found the collector do not match.

Linked unit module not found in: *filename*

The required library module is missing or has been corrupted. This message is generated when an incorrect version of the library is installed.

Memory requirement for build is greater than specified, an extra <n> bytes required at least

The amount of memory specified on a processor is not enough for the program to execute. An extra <n> bytes are required at least.

Memory size already specified

Memory size must be specified once only.

Memory size string invalid

Memory size must be given in decimal or hex. Hex numbers must be introduced by ‘#’ or ‘$’.

Memory size string too long

Specified memory size is too large.

More than one parameter statements

The collector expects only one parameter statement per processor. Either the file has been corrupted or the versions of icollect and configurer used are incompatible.

No debug and debug output file specified in command line

Options ‘D’ (disable debug) and ‘C’ (debug file name) cannot be used together.

No input file specified

One, and only one, input file must be specified on the command line.

No parameter descriptor present in input file: *filename*

The formal parameter descriptor in the input file is not present. This usually means that the process has not been linked with a main entry routine. This message will only appear if the collector is invoked with the ‘T’ option (unconfigured mode).

Output file already specified

More than one output file was specified. Specify only one.
Output filename too long

The maximum length allowed for the output filename is 256 characters.

Parameter descriptor error in input file: filename

The formal parameter descriptor in the input file is not of the correct form, indicating that the process interface is not one recognized by the collector. This message will only appear if the collector is invoked with the 'T' option (unconfigured mode). See section 3.3.

Print map file already specified

More than one print map file was specified. Specify one only.

Program configured for boot from ROM command line is boot from link

The specified configuration binary file was created for either ROM or RAM, and neither has been specified to icollect.

Program configured for running in RA mode command line is RO mode

Wrong mode specified, or incorrect option given to the configurer when the specified configuration binary file was created. RA and RO modes are mutually exclusive.

Program configured for running in RO mode command line is RA mode

Wrong mode specified, or incorrect option given to the configurer when the specified configuration binary file was created. RA and RO modes are mutually exclusive.

Require at least <ny> bytes at the top of memory for bootstrapping on processor <n>

The bootstrapping sequence requires an extra <ny> bytes at the top of memory. Once the bootstrapping has finished this memory is available to the user.

Rom size already specified

ROM size must be specified once only.

Rom size in input file and command line do not match

The ROM size specified on the command line does not match that specified to the configurer when the input file was created.

Rom size not specified

A ROM size must be specified because the input file is to be loaded into ROM.
3.12 Error messages

Rom size string invalid
   ROM size must be given in decimal.

Rom size string too long
   ROM size specified was too large.

Stack size already specified
   Stack size must be specified once only.

Stack size string invalid
   Stack size must be specified in decimal format.

Stack size string too long
   Specified stack size was too large.

Strange function or attribute for linked unit in: filename
   The collector has found an unfamiliar value in the input file. Either an old version of a tool was used in the creation of the input file, or the input file has been corrupted.

System error
   Host system error has occurred, probably when accessing a file. This message may be generated when a file is read and its contents seem to have changed or the file does not exist.

Unexpected end of file: filename
   One of the files specified in the configuration binary has ended prematurely. filename identifies the offending file. If the message ‘Suspect corrupted file’ is substituted for filename then the file is corrupted.

User bootstrap not allowed when program is configured
   User defined bootstrap loaders can only be used with single processor programs.

User bootstrap not allowed with rom option
   User defined bootstrap loaders cannot be used with ROM-loadable code.

User bootstrap type does not match that of linked unit
   Either the target processor type or the error mode of the bootstrap code does not match that of the input file.

3.12.3 Fatal errors

Internal error <message text>
   An internal error has occurred this should be reported to your local INMOS distributor or field applications engineer.
4 idebug — network debugger

This chapter is a reference chapter for the network debugger tool idebug. It describes the command line syntax and gives examples of the commands to use in different situations. It provides detailed reference information about the debugger symbolic debugging functions and Monitor page commands, and provides a list of error messages.

This chapter does not describe how to use the debugger, which is covered in Chapter 9 of the User Guide.

4.1 Introduction

The network debugger idebug is a comprehensive debugging tool for transputer programs. It can be run in post-mortem mode to determine the cause of failure in a halted program, or in interactive (breakpoint) mode to execute a program step-wise by setting breakpoints in the code. In either mode programs can be debugged from source code using the symbolic functions or from the machine code using the Monitor page commands.

Post-mortem debugging allows programs to be examined for the cause of failure after a transputer halts on error. The debugger locates the errant process in the program either by direct examination of the program image in transputer memory or by reading memory dump files. Processes running in parallel with the errant process anywhere on the network can be examined.

Interactive breakpoint debugging allows programs to be executed in a stepwise manner under interactive control. Breakpoints can be set within the code to cause the program to pause for the inspection of variables, channels, and processes; variables can be modified and the program continued with the new values.

The debugger can also be invoked on a dummy network to examine the static features of a program. The dummy network simulates the contents of memory locations and registers, and can also be used to explore the features of the debugger without running a real program.

4.2 Debugging the root transputer

idebug can be used to debug single and multitransputer programs. The techniques and commands to use when invoking the debugger differ slightly depending on whether or not the program (or a process forming part of the program) runs on the root transputer, and according to the debugging mode (post-mortem or breakpoint).
Two procedures are used to debug programs in post-mortem mode, depending on whether the application uses the root transputer. Programs that use the root transputer are referred to in this chapter as R-mode programs, and programs that do not use the root transputer are referred to as T-mode programs. Command line options are used to select the correct mode of operation for `idebug`.

To avoid the need for a memory dump, programs can be skip loaded over the root transputer using `iskip`. Skip loading requires at least one extra processor in the network (which will be used by the debugger) but speeds up debugging considerably and is the recommended method where more than one processor is available. Skip loading is described in detail in chapter 15 of this manual.

4.2.1 Board wiring

Before any program can be debugged in post-mortem mode, the transputer's Analyse signal must be asserted once, and once only. Because different procedures must be adopted for programs which do and do not use the root transputer, the debugger cannot assert the signal automatically and so the appropriate `iserver` option must be specified on the `idebug` command line.

Table 4.4 summarizes the command sequences to use for the two program modes on different board types.

4.2.2 Post-mortem debugging R-mode programs

Code running on the root transputer, and loaded with `iserver` directly, is debugged in post-mortem mode from a memory dump file which is specified by the 'R' option. The memory dump file must be created using the `idump` tool before the debugger is invoked. Other transputers in the network are debugged down links connected to the root transputer, in the normal way.

For R-mode programs, `idump` asserts the Analyse signal and the 'SA' option is not required on the `idebug` command line. In fact a second assertion of the signal would cause data in the memory to become corrupted. If `idump` is not used before the debugger is run then the debugger cannot load onto the root transputer and a server error is reported.

A description of the `idump` tool can be found in chapter 5 of this manual.

4.2.3 Post-mortem debugging T-mode programs

T-mode programs are loaded using `iskip` and subsequently debugged using the 'T' option to specify the root transputer link to which the network is connected. The 'SA' server option must also be added to the `idebug` command line in order to assert Analyse.

If the 'SA' option is not given, the debugger can not be booted onto the root transputer and the server aborts with an error message. The debugger should then be re-invoked with the correct options.
4.2.4 Post-mortem debugging from a network dump file

To suspend a post-mortem R or T debugging session without losing the original context, the Monitor page \([N]\) command can be used to dump the entire state of a network into a network dump file. The debugger can then be invoked using this file, without being connected to the network (although one transputer will still be needed to run the debugger).

**Note:** This option will only work for programs that have not been interactively (breakpoint) debugged.

Memory dump files and network dump files are not the same: the former contains a single processor's memory image while the later contains data about a complete network (they are also in different formats). The \(ilist\) tool can be used to determine the format of a dump file.

4.2.5 Debugging a dummy network

The debugger may be used to debug a program using dummy data. Using the debugger command line \(D\) option which simulates the contents of memory locations and registers, static features of a program may be examined. This is useful to determine processor connectivity and memory mapping for each processor in the network. Because memory locations etc. are simulated, this option only requires the root transputer in order to execute the debugger (even when used with a bootable file for a network of transputers).

The \(D\) option may also be used to explore most features of the debugger without running a program.

4.2.6 Methods for interactive breakpoint debugging

Interactive mode breakpoint debugging does not require use of the memory dump tool because the program is automatically skip loaded over the root transputer where the debugger is running. However, like all skip loads it requires an extra processor on the network.

4.3 Running the debugger

The debugger is invoked using the following command line:

```
idebug  bootablefile  {options}
```

where: `bootablefile` is the bootable file to be debugged.

**options** is a list of the options given in Table 4.1.

- Options must be preceded by `-` for UNIX-based toolsets and `/` for MS-DOS and VMS based toolsets.
- Options may be entered in upper or lower case and can be given in any order.
- Options must be separated by spaces.
Only one bootable file may be specified on the command line.

If no arguments are given on the command line a help page is displayed giving the command syntax and a list of command line options.

Command line parameters for programs being debugged interactively should not be entered on the debugger command line. The debugger will prompt for these parameters when the code being debugged is about to be started.

Note: idebug is unique amongst the toolset tools in that, when invoked with command line options, its driver program does not automatically reset (or analyze, as appropriate) the root transputer. This is due to the diversity of hardware configurations where the appropriate sequence may not be obvious to the driver. Because of this, the task of selecting the appropriate iserver command is delegated to the user.

Failure to supply the appropriate iserver reset (SR) or analyze (SA) options along with idebug command line options will result in iserver failing to boot idebug.

Only when invoked with no command line options at all will idebug automatically reset the root transputer and display its own help page.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Assert INMOS subsystem Analyse. Directs the debugger to assert Analyse on the sub-network connected to the root processor. Required when using B004 type boards.</td>
</tr>
<tr>
<td>AP</td>
<td>A replacement for the A option when running programs on boards from certain vendors. Asserts Analyse on the network connected to the root processor. Contact your supplier to see whether this option is applicable to your hardware. It does not apply to boards manufactured by INMOS.</td>
</tr>
<tr>
<td>B</td>
<td>Interactive breakpoint debug a network that is connected to the root processor via link linknumber. idebug executes on the root processor. Must be accompanied by the iserver 'SR' option.</td>
</tr>
<tr>
<td>C</td>
<td>Specify a processor type (e.g. T425) instead of a class (e.g. TA) for programs that have not been configured.</td>
</tr>
<tr>

Table 4.1 `idebug` command line options

### 4.3.1 Toolset file types read by the debugger

The debugger uses information within files produced by toolset tools in order to establish the hierarchy of components used to produce a bootable file.

Table 4.2 provides a list of file types used by the debugger. The table covers all languages which the debugger supports (FORTRAN, C, and occam).

<td>Root processor dump file (created by idump or isim) or network dump file (created by idebug).</td>
</tr>
</tbody>
</table>

Table 4.2 File types read by debugger

With the exception of a dump file which must have a .dmp filename extension, the debugger will accept different extensions for a particular file type. (For example the extensions used by imakef such as .tab which can be used instead of .tco).

4.3.2 Environment variables

idebug requires three environment variables to be set up on the host system (in addition to those required to run the iserver and to build a bootable file). These are listed in table 4.3. Details of how to set up these variables can be found in the Delivery Manual that accompanies this release.
 Contains the name of the file which defines key mappings for debugger symbolic functions and some monitor page commands. The name of the environment variable may be over-ridden by using the 'Q' command line option.

**IDEBUGSIZE** Defines the amount of memory available on the root transputer board. This variable must be specified for idebug to work correctly (idebug requires at least 1 Mbyte of available root transputer memory: it is strongly recommended that 2 Mbytes or more be available).

**IBOARDSIZE** The amount of memory available for the application program. Required for bootable single transputer programs (created from linked units using icollect with the 'T' option and without the 'M' option), where the memory size was not specified.

### Table 4.3 Environment variables used by idebug

#### 4.3.3 Program termination

If the program terminates by issuing the 'terminate' command to the server, the following message is displayed:

```
[Program has finished (after nnn seconds) - hit any key for monitor page]
```

The debugger can be re-entered after server termination by pressing any key. The final state of the network can be examined using the full range of symbolic and Monitor page commands.

The exit status returned by the program is displayed on the Monitor page.

If the program contains independent processes which require no communication with the server then the debugger allows the program to be resumed. In this case the debugger displays the following warning message:

```
[Warning: iserver terminated by user program: use CTRL-A for monitor page]
```

#### 4.4 Post-mortem mode invocation

To invoke the post-mortem debugger use the appropriate command from the following list. Command lines are shown in both in UNIX and MS-DOS/VMS formats.

**Note:** Commands are given for a B008 board wired subs (see section 4.7.1). For the commands and command sequences to use on other board types see section 4.7.2.
4.4 Post-mortem mode invocation

4.4.1 Debugging T-mode programs – option ‘T’

```
idebug bootablefile -t linknumber -sa
idebug bootablefile /t linknumber /sa
```

where: *bootablefile* is the program bootable file;

*linknumber* is the number of the link of the root processor which is connected to the network.

Use the ‘T’ option for programs that do not use the root transputer, that is those loaded by using *iskip*. The program is debugged from the program image that is resident in the memory of each transputer; the information about the rest of the network is extracted down the root transputer link. This method provides the fastest post-mortem debugging because the root transputer memory image is not saved. However, the option does require an extra transputer on the network. The ‘T’ option should be accompanied by the ‘SA’ option to assert Analyse on the network.

4.4.2 Debugging R-mode programs – option ‘R’

```
idebug bootablefile -r dumpfile
idebug bootablefile /r dumpfile
```

where: *bootablefile* is the program bootable file;

*dumpfile* is the root transputer memory dump file.

Use the ‘R’ option for programs that use the root transputer in a network. The dump file is created by using *idump*, which produces a dump of the program image on the root transputer only; the debugger extracts information about other transputers on the network (if applicable) via the root transputer’s links.

4.4.3 Debugging a network dump file – option ‘N’

```
idebug bootablefile -n netfile -sr
idebug bootablefile /n netfile /sr
```

where: *bootablefile* is the program bootable file;

*netfile* is a network dump file.

Use the ‘N’ option to debug programs without access to the original network of transputers. This is effectively debugging off-line. The network dump file is generated by the *idebug* Monitor page [N] command. Note: this can only be used for programs that have not been debugged interactively. The ‘N’ option should be accompanied by the *iserver* ‘SR’ option to reset the network.
4.4.4 Debugging a previous breakpoint session – option 'N'

```
idebug bootablefile -m linknumber -sa
idebug bootablefile /m linknumber /sa
```

where: `bootablefile` is the program bootable file;

`linknumber` is the number of the link of the root processor which is connected to the network.

Use the 'N' option to debug a previous breakpoint debugging session where either the network has crashed (error flag was set) or the host [BREAK] key was used to terminate the debugger. This option is the same as the 'T' option but informs the debugger the breakpoint runtime kernel is present. The 'N' option should be accompanied by the `iserver 'SA'` option to assert Analyse on the network. The same action may be achieved when using the debugger in interactive mode with a subsystem wired `subs` (see section 4.7.1) by use of the Monitor page [Y] command.

Note: Symbolic functions and Monitor page commands that support breakpointing are absent in post-mortem mode.

4.4.5 Re-invoking the debugger on single transputer programs

For programs running on a single transputer only and debugged from a memory dump file the debugger can be re-invoked on the same dump file by passing the 'SR' option to `iserver` from the `idebug` command line. This option is required to reset the transputer before loading the debugger program (the resetting is normally done by `idump`).

4.4.6 Debugging boot from ROM programs

Programs which are configured to boot from ROM and run in RAM may be debugged in post-mortem mode via a transputer link in a similar manner to that described in section 4.4.1. The debugger must be run on the root processor of the network (as specified to the configurer via the 'P' option) which must be set to boot from link while debugging.

```
idebug romcodefile -t linknumber -sa
idebug romcodefile /t linknumber /sa
```

where: `romcodefile` is the `.btr` output file produced by `icollect` for use by `ieprom`;

`linknumber` is the number of the link of the root processor which is connected to the network.

4.5 Interactive mode invocation

To run the debugger in interactive mode use one of the commands below.
Note: Commands are supplied for a B008 board wired subs. For the commands to use on other board types see Table 4.4.

```
idebug bootablefile -b linknumber -sr
idebug bootablefile /b linknumber /sr
```

where: 
- `bootablefile` is the program executable file;
- `linknumber` is the number of the root transputer link where the application network is connected.

In interactive mode `idebug` loads the bootable file directly onto the network and sets up a runtime kernel and `idebug` virtual link system on each processor used by the program. `iserver` is not required to load the program, but an extra processor is required to run the debugger; the program is in effect 'skip' loaded.

When first invoked in interactive mode, the debugger immediately enters the Monitor page where the [B] (Breakpoint Menu) command can be used to set breakpoints before the program is started.

### 4.6 Function key mappings

All the debugger symbolic functions, and some Monitor page commands, are assigned to specific keys on the keyboard by the ITERM file (the file specified by the environment variable `ITERM`). For the correct keys to use on your terminal consult the keyboard layouts provided in the Delivery Manual that accompanies this release.

ITERM files are supplied with the release for terminals commonly used with your host system but may also be created to suit your own requirements. Details of the ITERM file and an example listing which illustrates the format can be found in appendix D.

Key-mapped Monitor page commands are listed in section 4.9.7. A complete list of symbolic functions can be found in section 4.10.

### 4.7 Debugging programs on INMOS boards

On transputer boards the Analyse and Reset signals can be propagated from the root transputer in two ways, and this influences the options that must be used when debugging programs.

#### 4.7.1 Subsystem wiring

On transputer boards the subsystem signal is either propagated unchanged to all transputers on the network (known as wired down), or the signals are connected to the subsystem port (wired subs) from where they are controlled by the board’s root processor.
On B004 boards and other boards where subsystem is wired in the same way Analyse must be asserted on the network before transputers can be accessed by the debugger from the root processor. However, if Analyse is asserted more than once the program will be corrupted in transputer memory.

The wiring type can be identified by the hardware addresses of the three subsystem registers. On B004-type boards the addresses are as follows:

<table>
<thead>
<tr>
<th>Signal</th>
<th>Hardware address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset</td>
<td>#00000000</td>
</tr>
<tr>
<td>Analyse</td>
<td>#00000004</td>
</tr>
<tr>
<td>Error</td>
<td>#00000000</td>
</tr>
</tbody>
</table>

An example of a B004-type board is the IMS 8404 TRAM. For details of the subsystem wiring on other boards consult the Datasheet or board specification.

In addition, TRAM boards and B004 boards differ in the way the subsystem port is used. On TRAMs these subsystem signals are propagated to all transputers on the network, whereas on B004 boards the signals are not propagated at all.

The sample program assert.occ illustrates resetting a B004-type board. This program is supplied on the toolset examples directory.

### 4.7.2 Debugging options to use with specific board types

The conditions outlined above affect the commands that must be used when debugging T-mode and R-mode programs. Table 4.4 shows the command line options to use for different combinations of board type, subsystem wiring, and program mode.

For further details about loading programs see the chapters on loading and debugging in the User Guide (chapters 7 and 9).

### 4.7.3 Detecting the error flag in interactive mode

In interactive mode the debugger detects that a processor has its error flag set by use of the subsystem services. If the hardware is not wired up to use the subsystem services then the debugger is unable to detect when an error flag is set; this may cause the debugger to hang for no apparent reason. On such networks the iserver 'SE' option should be used to detect when an error flag has been set. Note, however, that detection of a set error flag will terminate the debugger without warning — the debugger can, however, be subsequently re-invoked in post-mortem mode.

Note: When using the debugger in interactive mode, the hardware should be set-up to use the subsystem services if possible.
4.8 Debugging programs on non-INMOS boards

If the hardware does not adhere to the INMOS subsystem convention then it is necessary to determine how the hardware is configured with respect to the subsystem and select the appropriate command line options.

It will probably be necessary to use the idebug command line 'S' option when breakpoint debugging in order to stop the debugger monitoring the subsystem.
error status, and the iserver 'SE' option to determine when the error flag has been set.

**Note:** Some non-INMOS boards use a specific subsystem convention which is supported by idebug, but which is different from the INMOS convention. To assert subsystem Analyse on such boards, use the 'AP' rather than the 'A' option. The board supplier should be able to say whether the 'AP' option is appropriate for their system.

### 4.9 Monitor page commands

This section lists and describes the debugger Monitor page commands. The commands are tabulated in alphabetical order for easy reference. Where a command invokes an option submenu the operation of each option in the submenu is described.

Monitor page commands are also listed for easy reference in the Handbook that accompanies this release.

#### 4.9.1 Command format

All Monitor page commands are either single letter commands or are invoked by a single function key press. Key mappings for the few general commands that use function keys can be found in the Delivery Manual that accompanies this release.

#### 4.9.2 Specifying transputer addresses

Many Monitor page commands require a memory address to be entered. Where there is a default value, this is displayed with the prompt. The default address is the last address specified or located to, and is used if [RETURN] is pressed without entering an address.

Addresses can be specified in decimal or hexadecimal format. Hexadecimal numbers must be given as a sequence of hexadecimal digits preceded by the characters '!', '$', or '@'. The '!' and '$' characters are used to prefix a full hexadecimal address. The '@' character adds MOSTNEG INT to the hexadecimal value using modulo arithmetic. This is useful when specifying transputer addresses which are signed and start at MOSTNEG INT. For example, %70 is interpreted as #80000070 on a 32 bit transputer, and as #8070 on a 16 bit transputer.

Address may also be specified relative to the Iptr or Wptr (derived from the current Wdesc) currently displayed in the monitor page. One of the following forms may be used:

- `i+n` or `i-n`: for addresses relative to Iptr — in this case `n` is a byte offset.
- `w+n` or `w-n`: for addresses relative to Wptr — in this case `n` is a word offset.

#### 4.9.3 Scrolling the display

Several commands mapped by the ITERM file (see below) may be used to scroll certain of the Monitor page displays. Cursor keys may also be used.
4.9.4 Editing functions

The following string editing functions are available for on-screen editing of strings for certain commands:

- **START OF LINE**: Move the cursor to the beginning of the string.
- **END OF LINE**: Move the cursor to the end of the string.
- **DELETE LINE**: Delete the string.
- **Left Arrow**: Move the cursor left one character.
- **Right Arrow**: Move the cursor right one character.
- **Delete**: Replace the current string with the string used in the previous invocation of the command.
- **Delete Left Character**: Delete the character to the left of the cursor.
- **Return**: Enter the string.

Note: **START OF LINE**, **END OF LINE**, **DELETE LINE**, and **Delete** are mapped by the ITERM file to specific keys on the keyboard. Details of the key mappings on your terminal can be found in the Delivery Manual that accompanies this release. **Delete** will not be applicable to some commands.

4.9.5 Commands mapped by ITERM

Certain Monitor page commands are mapped to specific keys on the terminal by the ITERM file. Commands mapped in this way include keys which are used to scroll the display (see below), commands which produce the same effect in both debugging modes, and the commands **TOP**, **RETRACE**, **RELOCATE** and **RESUME** which invoke the corresponding symbolic mode functions.

The keys to use for all Monitor page commands mapped by ITERM can be found by consulting the keyboard layouts supplied in the Delivery Manual.

4.9.6 Summary of commands

<table>
<thead>
<tr>
<th>Key</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A*</td>
<td>ASCII</td>
<td>View a region of memory in ASCII.</td>
</tr>
<tr>
<td>B†*</td>
<td>Breakpoint</td>
<td>Display the Breakpoint menu enabling breakpoints to be set, cleared or listed.</td>
</tr>
</tbody>
</table>

† = Interactive mode only.
* = String editing functions available for these commands, see section 4.9.4.
<table>
<thead>
<tr>
<th>Key</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Compare</td>
<td>Compare the code on the network with the code that should be there to ensure that the code has not been corrupted.</td>
</tr>
<tr>
<td>D*</td>
<td>Disassemble</td>
<td>Display the transputer instructions at a specified area of memory.</td>
</tr>
<tr>
<td>E</td>
<td>Next Error</td>
<td>Switch the current display information to that of the next processor in the network which has halted with its error flag set.</td>
</tr>
<tr>
<td>F*</td>
<td>Select file</td>
<td>Select a source file for symbolic display using the filename of the object file produced for it.</td>
</tr>
<tr>
<td>G</td>
<td>Goto process</td>
<td>Goto symbolic debugging for a particular process.</td>
</tr>
<tr>
<td>H*</td>
<td>Hex</td>
<td>View a region of memory in hexadecimal.</td>
</tr>
<tr>
<td>I*</td>
<td>Inspect</td>
<td>View a region of memory in a symbolic type. Types are expressed as standard occam types.</td>
</tr>
<tr>
<td>J†*</td>
<td>Jump</td>
<td>Start or resume the application program.</td>
</tr>
<tr>
<td>K</td>
<td>Processor names</td>
<td>Display the names and types of all processors in the network.</td>
</tr>
<tr>
<td>L</td>
<td>Links</td>
<td>Display instruction pointers and process descriptors for the processes currently waiting for input or output on a transputer link, or for a signal on the Event pin.</td>
</tr>
<tr>
<td>M</td>
<td>Memory map</td>
<td>Display the memory map of the current processor.</td>
</tr>
<tr>
<td>N*</td>
<td>Network dump</td>
<td>Copy the entire state of the transputer network into a 'network dump' file in order to allow continued (off-line) debugging at a later date.</td>
</tr>
<tr>
<td>O*</td>
<td>Specify process</td>
<td>Resume the source level symbolic features of the debugger for a particular process.</td>
</tr>
<tr>
<td>P*</td>
<td>Processor</td>
<td>Switch the current display information to that of another processor.</td>
</tr>
<tr>
<td>Q</td>
<td>Quit</td>
<td>Leave the debugger and return to the host operating system.</td>
</tr>
<tr>
<td>R</td>
<td>Run queues</td>
<td>Display instruction pointers and process descriptors of the processes on either the high or low priority active process queue.</td>
</tr>
<tr>
<td>S†</td>
<td>Show messages</td>
<td>Display the Messages menu enabling the default actions of the debugger to debug support functions to be changed.</td>
</tr>
</tbody>
</table>

† = Interactive mode only.
* = String editing functions available for these commands, see section 4.9.4.
### 4.8 Debugging programs on non-INMOS boards

<table>
<thead>
<tr>
<th>Key</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Timer queues</td>
<td>Display instruction pointers, the process descriptors and the wake-up times of the processes on either the high or low priority timer queue.</td>
</tr>
<tr>
<td>U†</td>
<td>Update</td>
<td>Update the monitor page display to reflect the current state of the processor.</td>
</tr>
<tr>
<td>V</td>
<td>Process names</td>
<td>Display the memory map of processes on the current processor.</td>
</tr>
<tr>
<td>W†*</td>
<td>Write</td>
<td>Write to any portion of memory in a symbolic type. Types are expressed as standard OCCAM types.</td>
</tr>
<tr>
<td>X</td>
<td>Exit</td>
<td>Return to symbolic mode.</td>
</tr>
<tr>
<td>Y†</td>
<td>Postmortem</td>
<td>Change an interactive breakpoint debugging session into a post-mortem debug session.</td>
</tr>
<tr>
<td>Z</td>
<td>Virtual links</td>
<td>Display instruction pointers and process descriptors for processes waiting on the configurer's software virtual links.</td>
</tr>
<tr>
<td>?</td>
<td>Help</td>
<td>Display help information.</td>
</tr>
</tbody>
</table>

† = Interactive mode only.
* = String editing functions available for these commands, see section 4.9.4.

#### 4.9.7 Symbolic-type commands

- **HELP**: Display help information.
- **REFRESH**: Re-draw the screen.
- **RELOCATE**: Switch to symbolic mode and perform symbolic relocate.
- **RESUME**: Restart a process stopped at a breakpoint.
- **RETRACE**: Switch to symbolic mode and perform symbolic retrace.
- **TOP**: Locate to the last instruction executed on the current processor.

Key bindings for these commands on specific terminal types can be found in the rear of the Delivery Manual.

#### 4.9.8 Scroll keys

- **LINE UP**: Scroll the currently displayed memory, disassembly, queue, or list.
**LINE DOWN** Scroll the currently displayed memory, disassembly, queue, or list.

**PAGE UP** Scroll the currently displayed memory, disassembly, queue, or list.

**PAGE DOWN** Scroll the currently displayed memory, disassembly, queue, or list.

**TOP OF FILE** Go to the top of the currently displayed processor name list, or software virtual link list.

**END OF FILE** Go to the end of the currently displayed processor name list, or software virtual link list.

▲ Scroll the currently displayed memory, disassembly, queue, or list.

▼ Scroll the currently displayed memory, disassembly, queue, or list.

◄ Scroll the currently displayed processor left.

► Scroll the currently displayed processor right.

Key bindings for these commands on specific terminal types can be found in the rear of the Delivery Manual.

### 4.9.9 Monitor page command descriptions

**ASCII**

This command displays a segment of transputer memory in ASCII format, starting at a specific address. If no address is given the last specified address is used. Specify a start address after the prompt:

**Start address** (#hhhhhhhh) ?

Either press [RETURN] to accept the default (last specified) address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by ‘#’, or the short form ‘%h...h’.

The memory is displayed in blocks of 16 rows of 32 ASCII bytes, each row preceded by an absolute address in hexadecimal. Bytes are ordered from left to right in each row. Unprintable characters are substituted by a full stop.

The scroll keys (section 4.9.7) can be used to scroll the display.
Breakpoint menu (interactive mode only)

This command invokes the Breakpoint Menu:

Breakpoint Menu
S - Set a breakpoint on this processor
T - Toggle a breakpoint on this processor
C - Clear a numbered breakpoint
A - Clear all breakpoints on all processors
B - Clear all breakpoints on this processor
E - Set a breakpoint at all entries this processor
G - Set a breakpoint at all entries all processors
M - Set a breakpoint at all main () this processor
L - List all breakpoints and hits
P - List all breakpoints and hits on this processor
Q - Quit this option

Breakpoint option (A,B,C,E,G,L,M,P,Q,S,T) ?

Options are selected by entering one of the single letter commands. A selected option can be cancelled by pressing [RETURN] with no typed input when it prompts for an address or a breakpoint number.

The 'E' and 'G' options, which set breakpoints at the entry point of all configuration level processes, are mainly for use with occam programs where the entry point of the program is the start of the top-level process. For non-configured occam programs the entry point is the first procedure called when the program starts. For configured occam programs the entry point is the configuration level code.

The 'M' option is intended for languages which have run-time support and a known entry point to the application code (such as main () in C, or the FORTRAN main program). This option sets a breakpoint at all the program entry points on the current processor.

Note: for processors which do not have hardware breakpoint support the debugger will not set breakpoints in high priority configuration level processes when the 'E', 'G' or 'M' options are used.

Breakpoints are assigned a unique number which must be used with the 'C' option. Numbers are given on the List Breakpoints displays.

In addition, the List Breakpoint displays provide information about the processor the breakpoint has been placed on (Proc: ), the address of the breakpoint (Addr: ), the number of times the breakpoint has occurred (Hits: ) and for breakpoints set in symbolic mode the filename and line number they correspond to. For example:

4) Proc: 0, Addr: #8000408E, "facs.c":201
    Hits: 3
This display means that breakpoint number 4 on processor 0 at address #8000408E (which corresponds to line number 201 of the file “facs.c”) has been hit three times.

Note: Only breakpoints which are set in symbolic mode (at the beginning of a statement) are properly supported. Setting breakpoints at arbitrary addresses using the ‘s’ option may cause incorrect execution of the program.

Note: Breakpoints should not be set in high priority processes on processors without hardware breakpoint support (M212, T212, T222, T414, and T800). The E, G and M options will not set a breakpoint in a high priority (configuration level) process on these processors.

**Compare memory**

This option compares the code actually in memory on the network with the code that was loaded, to check that memory has not become corrupted.

Note: This option treats breakpoints as corrupted code.

The following menu is displayed:

```
Compare memory
Number of processors in network is : n

A - Check all network processors for discrepancies
B - Check this processor for discrepancies
C - Compare memory of this processor on screen
D - Find first error on this processor
Q - Quit this option

Compare memory option (A,B,C,D,Q) ?
```

Type one of the options A, B, C, D, or Q. Option ‘Q’ returns to the Monitor page.

**Checking the whole network - option A**

Option ‘A’ checks all the processors in the network and displays a summary of the discrepancies found.

If there are no errors the following message is displayed:

```
Checked all processors in network OK
```

If any errors are detected the number of errors is given along with the address of the first error found and the name of the processor on which it occurred.
Checking a single processor - option B

Option 'B' checks just the current processor. In all other respects it is similar to option 'A'.

Compare memory on screen - option C

Option 'C' displays the actual and expected code for each address in the program code area of the current processor. Discrepancies are marked with an asterisk ('*').

Memory is checked in blocks of 128 bytes. At the end of each block, type either 'Q' to quit, or [SPACE] to read and display the next block.

The format of the display is similar to the following example:

```
#800001234  :  0011223344556677
#80000123C  :  0011223344556677
#800001244  :  0011223344556677
#8000012AC  :  0011223344556677
```

Processor Code      Correct Code

```
#800001234  : 7766554433221100 *
#80000123C  : 0011223344556677
#800001244  : 7766554433221100 *
#8000012AC  : AABBCDDDEFF0011 AABBCDDDEFF0011
```

Press [DOWN] to scroll memory, [SPACE] for next error, or Q to quit:

Pressing [SPACE] automatically invokes option 'D' - Find first error... (see below).

Find first error - option D

Option 'D' searches the current processor's memory for the first occurrence of a discrepancy. If a discrepancy is found the display is the same as in option 'C' above, and the memory can be checked and displayed as in 'Compare memory on screen'.

Disassemble memory

The Disassemble command disassembles memory into transputer instructions. Specify an address at which to start disassembly after the prompt:

```
Start address (#hhhhhhhh) ?
```

Either press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by '#', or the short form '%h...h'.

The memory is displayed in batches of sixteen transputer instructions, starting with the instruction at the specified address. If the specified
address is within an instruction, the disassembly begins at the start of that instruction. Where the preceding code is data ending with a transputer 'pfix' or 'nfix' instruction, disassembly begins at the start of the pfix or nfix code.

Each instruction is displayed on a single line preceded by the address corresponding to the first byte of the instruction. The disassembly is a direct translation of memory contents into instructions; it neither inserts labels, nor provides symbolic operands.

The scroll keys (section 4.9.7) can be used to scroll the display.

**Next Error**

Next Error searches forward through the network for the next processor which has both its error and halt-on-error flags set. Processors are searched in the same order as they are listed by the 'K' command, starting from the current processor and wrapping round. If a processor is found with both flags set the display is changed to the new processor as if the 'P' option had been used. Press [TOP] to display the source line which caused the error.

If there is only one processor in the network then a message to this effect is displayed.

**Select source file**

This command enables a program source file to be displayed within the symbolic debugging environment for a particular processor. This allows breakpoints to be set in modules which have not yet been reached in the program’s execution. (Source which has not yet been executed cannot be displayed using the 'O' or 'G' options because the Iptr and Wdesc addresses are not yet known.)

When the source file is first displayed, the cursor is placed on the first source code line which generates object code. If the start of the source file contains an include file it is possible for the debugger to locate this instead. In order to locate the intended source file, use the [EXIT FILE] key to exit the include file.

The select source file command may also be used to browse source files rather like the [CHANGE FILE] symbolic function. However, unlike [CHANGE FILE] it allows some of the symbolic debugging operations to be used.

**Note:** Editing keys may be used with this command to provide a simple history mechanism (see section 4.9.4).

For mixed language programs, the behavior of this command will differ depending on whether icconf or the OCCAM configurer occonf has
been used to configure the program. (*icconf* is supplied with FORTRAN and ANSI C toolsets, *occconf* with OCCAM toolsets.)

The differences in the behavior are described below:

**Behavior of command when no configurer or *icconf* is used**

If a processor has been configured to contain more than one process, this option first prompts for the process number corresponding to the source code:

*Select process number (0 - N) ?*

The range of numbers displayed in brackets are process numbers assigned by the debugger to different processes on the processor. The process numbers assigned to process names by the debugger can be determined by using the Monitor page Process Name ('V') option before invoking the ‘F’ command.

Once a valid process number has been supplied (if applicable), the debugger prompts for the filename of the compiled object module. The full object filename (including extension — conventionally .tco) must be supplied.

*Object module filename ?*

The object filename must be specified because the debugger extracts the source code filename from the debug information in the compiled object file.

Note: Editing keys may be used with this command to provide a simple history mechanism (see section 4.9.4). At each prompt this command may be aborted by pressing [RETURN] with no typed input.

**Behavior of command when *occconf* is used**

The debugger first prompts for the filename of a linked object module. The full linked filename (including extension — conventionally .lk) must be supplied.

*Linked unit filename ?*

The linked filename must be specified because the debugger needs to know which linked unit (incorporated by a configurer #USE directive) contains the object code from the source file to be displayed.

The debugger then prompts for the filename of a compiled object module contained within the selected linked unit. The full object filename (including extension — conventionally .tco) must be supplied.

*Object module filename ?*
The object module filename must be specified because the debugger extracts the source code filename from the debug information in the compiled object file.

At each prompt this command may be aborted by pressing [RETURN] with no typed input.

**Go to process**

This command locates to the source code for any process which is currently shown on the screen. Any process displayed by using the [T], [L], [R], [T], or [Z] commands may be selected.

The cursor is positioned next to the Iptr value and permitted responses are listed on the screen, as follows:

```
Goto process - use [CURSOR] then [RETURN], or 0 to F, (I)ptr, (L)o or (Q)uit
```

To select a process and display the source code, move the cursor to a displayed Iptr value and press [RETURN], or use one of the following short-cuts:

- The [I] option locates to the current process (the process corresponding to the displayed Iptr and Wdesc values).
- If currently in high priority, the [L] option can be used to locate to the interrupted low priority process (the process corresponding to the displayed IptrIntSave and WdescIntSave values).
- The hex numbers [0] — [F] will locate to the process corresponding to one of the 16 lines displayed on the right hand side of the Monitor page (the entries in the timer or run queues, or processes waiting on links).

Type 'Q', [FINISH], or [REFRESH] to abort this command.

**Hex**

The Hex command displays memory in hexadecimal. Specify the start address after the prompt:

```
Start address (#hhhhhhhh) ?
```

Press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by '#' , or the short form '%h...h'. If the specified start address is within a word, the start address is aligned to the start of that word.
The memory is displayed as rows of words in hexadecimal format. Each row contains four or eight words, depending on transputer word length. Words are displayed in hexadecimal (four or eight hexadecimal digits depending on word length), most significant byte first.

For a four byte per word processor the sequence of bytes in a single row would be:

```
3 2 1 0 7 6 5 4 11 10 9 8 15 14 13 12
```

For a two byte per word processor, the ordering would be:

```
1 0 3 2 5 4 7 6 9 8 11 10 13 12 15 14
```

Words are ordered left to right in the row starting from the lowest address. The word specified by the start address is the top leftmost word of the display.

The address at the start of each line is an absolute address displayed in hexadecimal format.

The scroll keys (section 4.9.7) can be used to scroll the display.

### Inspect memory

The Inspect command can be used to inspect the contents of an entire array. Specify a start address after the prompt:

```
Start address (#hhhhhhhh) ?
```

Either press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by 'h', or the short form '%h ... h'.

When a start address has been given, the following prompt is displayed:

```
Typed Memory Dump
```

```
0 - ASCII
1 - INT
2 - BYTE
3 - BOOL
4 - INT16
5 - INT32
6 - INT64
7 - REAL32
8 - REAL64
9 - CHAN
Q - Quit this option
```

Which occam type (1 - INT) ?
Give the number corresponding to the type of data to be displayed, press \texttt{RETURN} to accept the default type or enter \texttt{Q} to quit this option.

The types correspond to formal occam types as defined in the \textit{occam 2 Reference Manual}. occam equivalences of C and FORTRAN types are listed in table 4.5.

<table>
<thead>
<tr>
<th>C</th>
<th>FORTRAN</th>
<th>occam</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>long double</td>
<td>REAL*8</td>
<td>REAL64</td>
</tr>
</tbody>
</table>

Table 4.5 Type equivalents for inspect command

ASCII arrays are displayed in the format used by the Monitor page command \texttt{A}. Other types are displayed both in their normal representation and hexadecimal format.

The memory is displayed as sixteen rows of data. The address at the start of each line is an absolute address displayed as a hexadecimal number. The element specified by the start address is on the top row of the display.

Start addresses are aligned to the nearest valid boundary for the type, that is: BYTE and BOOL to the nearest byte; INT16 to the nearest even byte; INT, INT32, INT64, REAL32, REAL64, and CHAN to the nearest word.

The scroll keys (section 4.9.7) can be used to scroll the display.

\textbf{Jump into and run program}

This command starts up a program from the Monitor page, or restarts a process which has encountered a breakpoint or has been stopped by one of the debug support functions (for details of these functions see the appropriate Language and Libraries Reference Manual).

\textbf{Starting a program}

When starting a program the debugger converts (patches) the configuration external channels (those assigned to links) for each processor into
virtual channels for use with the debugging kernel. This action is indicated by an activity indicator.

When the patching is complete the debugger prompts for a command line for the program:

Command line:

Simply press [RETURN] if the program does not require any command line parameters. The program will then start running.

Resuming from a breakpoint

When jumping into and resuming a program from a breakpoint, in the monitor page, the following menu is displayed:

Jump into Application

R - Resume process stopped at a breakpoint
O - Resume monitoring of network
   (abandon process stopped at a breakpoint)
J - Restart process at a different location
Q - Quit this option

Which option (J,O,Q,R) ?

Note: the [RESUME] key can be used as an alternative to using this command with the R option.

Resuming from debug support functions

When resuming from one of the debug support functions, the following submenu is displayed:

Jump into Application

O - Resume monitoring of network
   (abandon process stopped at a program error)
J - Restart process at a different location
Q - Quit this option

Which option (J,O,Q) ?

Jump options

The four Jump options are described in the following table:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Restarts the process that encountered the breakpoint.</td>
</tr>
<tr>
<td>O</td>
<td>Ignores the stopped process and resumes monitoring the network for other process activity. <strong>Note:</strong> When a process has stopped, other processes continue to run until they either encounter a breakpoint or program error (i.e. one of the debugging support functions), or become dependent on the stopped process. <strong>Note:</strong> Using this option for a process stopped on a breakpoint removes the process forever.</td>
</tr>
<tr>
<td>J</td>
<td>Restarts the process from a different location. Only use this option if you are confident that the program can be resumed from the new location; resumption from most locations will corrupt the program.</td>
</tr>
<tr>
<td>Q</td>
<td>Quits the Jump sub-menu.</td>
</tr>
</tbody>
</table>

**Editing keys**

Editing keys may be used with this command when entering the command line parameters starting the program, see section 4.9.4.

**Processor names**

This command displays the internal processor numbers corresponding to processor names used in the configuration description and the corresponding processor type. Processor numbers must be given when selecting specific processors for display.

The scroll keys (section 4.9.7) can be used to scroll the display.

**Note:** The debugger displays only the first 19 characters of the processor name. If this is a problem then names should be made unique within the first 19 characters.

**Links**

The Links command displays the instruction pointer, workspace descriptor, and priority of the processes waiting for communication on the links, or for a signal on the Event pin. If no process is waiting, the link is described as 'Empty'. Link connections on the processor, and the link from which the processor was booted, are also displayed.

If a processor uses software virtual links then the title line of the data displayed appears as:

**Link Information (virtual links present)**
This is to warn that the link state information may be for software virtual processes which cannot be located to in the normal manner. In this case it is more useful to use the Monitor page command to display the software virtual links instead.

For configured programs, the debugger checks that the link the root processor has been booted from matches that expected by the configurer. If it does not, the following message is displayed:

**Booted from link n < Should be link m !!! >**

The format of the display is similar to the following:

```
Link Information
Link 0 out Empty
Link 1 out Empty
Link 2 out Iptr: #80000256 Wdesc: #80000091 (Lo)
Link 3 out Empty
Link 0 in Empty
Link 1 in Empty
Link 2 in Iptr: #80000321 Wdesc: #80000125 (Lo)
Link 3 in Iptr: #80000554 Wdesc: #80000170 (Hi)
Event in Empty

Link 0 connected to Host
Link 1 not connected
Link 2 connected to Processor 1, Link 1
Link 3 connected to Edge

Booted from link 0
```

**Memory map**

The Memory map command displays the memory map of the current processor along with the mode that `idebug` is currently in. The mode may be one of:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interactive Mode</td>
<td>Interactive breakpoint debugging session</td>
</tr>
<tr>
<td>Postmortem Interactive Mode</td>
<td>Postmortem debugging session of a previous interactive debugging session.</td>
</tr>
<tr>
<td>Postmortem Mode</td>
<td>Postmortem debugging session either down a transputer link or from a dump file.</td>
</tr>
<tr>
<td>Dummy Session</td>
<td>Dummy debugging session</td>
</tr>
</tbody>
</table>
The display includes the address ranges of on-chip RAM, program code, configuration code, stack (workspace) and vectorspace, the sizes of each component in bytes rounded up to the nearest 1K bytes, total memory usage, and the address of MemStart (the first free location after the RAM reserved for the processor’s own use).

Also displayed is the total memory usage. Total memory usage indicates the amount of memory used by a user program. Note that this may include a region of memory at the beginning of freespace; this area is used for configuration code before execution of a user program starts (this memory may be safely overwritten by the user program because the configuration code finishes executing before the user code starts).

The minimum memory size specified to the configurer or the collector, or as defined in IBOARDSIZE as appropriate, must be at least as large as the total memory usage for each processor.

Also displayed is the maximum number of processors that can be accommodated by the debugger’s buffer space. This will depend on the amount of memory on the root processor, indicated to the debugger by the host environment variable IDEBUGSIZE.

The address of MemStart is the value actually found on the transputer in the network. If this does not correspond to that expected by the configuration description, for example if a T414 was found when a T805 was expected, the following message is displayed:

```
MemStart: #80000048 (T414)?
MemStart should be: #80000070 (T805) <<!>>
```

If an incorrect MemStart is detected the symbolic functions may not work correctly. In this case the program should be rebuilt for the correct processor types before re-invoking the debugger.

### Network dump

The Network dump command saves the state of the transputer network for later analysis. If the debugger is terminated without creating a network dump file, debugging cannot continue from the same point without re-running the program. This is because the debugger itself overwrites parts of the memory on each transputer in the network.

**Note:** This command cannot be used in interactive mode (`idebug command line option 'B'`) or when post-mortem debugging a breakpoint session (`idebug command line option 'M'`).

Once a network dump file has been created, debugging can continue from the dump file, and the debugger does not need to be connected to the target network.
Before the dump file is created, the debugger calculates the disk space required, and requests confirmation. The size of the file depends on how much of each processor's memory is actually used in running the program, and is displayed as follows:

```
Create network dump file
Number of processors to dump: 2
File size excluding Freespace: 112604 bytes
File size including Freespace: 2097308 bytes

Continue with network dump (Y,N) ?
```

To continue with the network dump, type 'Y'.

The debugger will then ask whether to include freespace in the dump file (this is not normally required for configured programs).

```
Do you wish to include Freespace (Y,N) ?
```

Type 'Y' or 'N' as appropriate and specify a filename after the prompt:

```
Filename ("network.dmp" or "QUIT") ?
```

Press [RETURN] to accept the default filename, enter a filename (any extension will be replaced by '.dmp'), or type 'QUIT' (uppercase) to exit.

If the file already exists, confirmation is asked for:

```
File "network.dmp" already exists
Overwrite it (Y,N) ?
```

If 'N' is entered then a new filename is asked for.

While the dump file is being written, a message is displayed at the terminal. For example:

```
Dumping network to file "network.dmp" ...
Processor 1 (T800)
Memory to dump: 10456 bytes ...
```

Specify process

This command returns to symbolic debugging, either at the same source line, or at another location. It can be used to locate to any source line, whether or not a process is waiting or executing there. To ensure the debugger locates to a valid process, it is better to use the 'G' command.

To return to symbolic debugging, the debugger requires values for Iptr and Wdesc. Specify Iptr after the prompt:

```
Iptr (#hghhhhhhh) ?
```
The default displayed in parentheses is the last line located to on this processor, or the address of the last instruction executed. Either press \[RETURN\] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by '#', or the short form '%h...h'.

Useful process addresses can be determined using the [L], [R], or [T] commands to display processes. These processes can, however, be more easily located by using the [G] command. The value of the saved low priority Iptr can also be used.

If the Iptr is not within the program body, the debugger indicates the type of code to which it corresponds.

After the Iptr has been entered the debugger prompts for the value of the process descriptor:

\[\text{Wdesc} \text{ (#hhhhhhhh)} \text{ ?}\]

If a displayed Iptr was specified, its corresponding Wdesc is offered as a default. Press [RETURN] to accept the default, or specify a value in the same format as the Iptr.

If no symbolic features other than a single 'locate' are required, then Wdesc is not needed and the default can be accepted.

If an invalid Wdesc is given, most of the symbolic features will not work, or will display incorrect values. However, the values of scalar constants and some other symbols can still be determined.

Any attempt to inspect or modify variables or channels, or to backtrace, will give one of the following messages:

\[\text{Wdesc is invalid - Cannot backtrace}\]
\[\text{Wdesc is invalid - Cannot Inspect variables}\]
\[\text{Wdesc is invalid - Cannot Modify variables}\]
\[\text{Wdesc is invalid - Cannot auto backtrace out of library}\]

Once the Iptr and Wdesc have been supplied, the debugger displays the source code at the required location, and the full range of symbolic features are available.

**P**

**Change processor**

This command changes to a different processor in the network. Specify the processor number after the prompt:

\[\text{New processor number (0 - n)} \text{ ?}\]

To determine the mapping between the processor number and the processor name used in the configuration file, use the 'K' command. If the
processor exists the display is changed to provide information about the specified processor. If the new processor's word length is different from that of the previous processor, the start address is reset to the bottom of memory. If the processor is not in the configuration, the following message is displayed:

\[\text{Error: That processor number does not exist}\]

To abort the command press [RETURN] with no input.

If there is only one processor in the network, an appropriate message is displayed.

The scroll keys (section 4.9.7) can be used to change the displayed processor. The sequence of processors is the same as that displayed by the 'K' command.

**Quit**

This command quits the debugger and returns to the operating system. Once quit, the debugger cannot be used to debug the same program without reloading the program unless a 'network dump' file has been created. This is because using the debugger overwrites some of the contents of the network.

If the command line option XQ has been used the debugger will ask for confirmation before quitting.

**Run queues**

This command displays Iptes and Wdescs for processes waiting on the processor's active process queues. If both high and low priority front process queues are empty, the following message is displayed:

\[\text{Both process queues are empty}\]

If neither queue is empty, the debugger ask which queue is to be displayed:

\[\text{High or low priority process queue? (H, L)}\]

Type 'H' or 'L' as required. If only one queue is empty, the debugger displays the non-empty queue.

The screen display is paged. The scroll keys (section 4.9.7) can be used to scroll the display.

**Note:** In interactive mode this command may show the details of a process more than once. The string '<!' next to the queue heading serves as a reminder that this may occur.

Processes which belong to the debugging kernel are also displayed and identified with the string '(Runtime kernel)'.

72 TDS 367 01

March 1993
Show debugging messages

This command is used to enable and disable debugging messages and prompts. It invokes the following submenu:

Show Messages Menu

B -- Show message for breakpoints : ON
D -- Show debug messages : ON
E -- Show message for program errors : ON
Q -- Quit this option

which option (B,D,E,Q) ?

Options B and E control the display of prompts when a breakpoint or program error (i.e. one of the debug support library functions debug_assert() and debug_stop(), etc.) is encountered. Disabling these options ensures that the debugger is entered on a breakpoint or error without requesting confirmation.

Option D controls the display of debugging messages inserted with the library functions debug_message(), etc.

Timer queues

This command displays Iptrs, Wdescs, and wake-up times for processes waiting on the processor's timer queues. Prompts and displays are similar to those for the Run queues command.

Update registers

This command updates the clock and status display (e.g. run queues, links) for the current processor. It enables the activity of other processes to be monitored while one process is stopped at a breakpoint or error.

Process memory map

This command provides details on each process resident on a processor. This consists of user processes, and configuration processes for virtual channels (if applicable: their names begin with a '%'); it does not include the debugging kernel used by the debugger when interactive breakpoint debugging (this information is shown by the Memory Map option).

A process is assigned a number by the debugger in order to identify the process when using certain other monitor page options. In addition to the process number, the following details are provided: the name of the process, the priority the process starts in, and the process stack and code areas. Note that for non-configured C programs, the stack area displayed is not that used by the program (the actual stack used is provided by the freespace area).
An example output for two configured processes is shown below:

```
Process Memory Map
Process 0 : "occam_process"
  Initially : High priority
  Stack : #80005000 - #80005023
  Code : #8000A038 - #8000A04B

Process 1 : "c_process"
  Initially : Low priority
  Stack : #80005024 - #8000A037
  Code : #8000A04C - #8000D73B
```

Note: The debugger displays only the first 19 characters of the process name. If this is a problem then names should be made unique within the first 19 characters.

Note: Processes placed on a processor to provide software virtual links have names starting with ‘%’.

**Write to memory**

This command writes a value to a specified address. Values must be specified in the current type (the type used in the previous Monitor page Inspect command), or the OCCAM type INT if the type was a CHAN or the Disassemble or Hex options have been used after an Inspect.

**Exit**

This command returns to symbolic mode and locates to the current address.

**Enter post-mortem debugging**

This command allows the debugger to be switched into post-mortem mode when the program crashes (a process sets the error flag on any processor). Halted processors prevent the breakpoint debugger from accessing the network correctly and debugging must continue in post-mortem mode. It has the same effect as re-invoking the debugger with the command line ‘M’ option.

If the program has not already started, then the debugger prompts for confirmation:

```
The program has not started - are you sure (Y,N) ?
```

If the program has not crashed, the debugger prompts for confirmation:

```
The program has not crashed - are you sure (Y,N) ?
```

If checking of the subsystem error status is disabled (with the command line ‘S’ option), then the prompt is:

```
Unable to detect if the program has crashed - are you sure (Y,N) ?
```

Typing ‘y’ continues the operation, typing ‘n’ aborts it.

This command will only work if the subsystem is wired subs (see section 4.7.1). For a subsystem wired down, it is necessary to quit and restart the debugger using the Monitor page ‘m’ command line option (instead of the previous breakpoint command line ‘b’ option).

Note: State information for a process that has stopped (on breakpoint or error) will be lost when switching from breakpoint to post-mortem mode. If the information is important it should be noted before switching modes.

Display software virtual links

This command displays instruction pointers and process descriptors for the processes currently waiting on software virtual links placed onto a processor by the configurer. All of the virtual output links (displayed as Vout \( N \)) are displayed followed by all of the virtual input links (displayed as Vin \( N \)).

The scroll keys (section 4.9.7) can be used to scroll the display.

In order to establish the mapping of user channels onto software virtual links on a particular processor, you should use the configurer information ‘i’ option when configuring.

Note: all low priority user processes using software virtual links will be promoted temporarily to high priority when they communicate. The debugger cannot tell if they were originally at high or at low priority. If you need to specify a low priority Wdesc then use the displayed value with the least significant bit set (e.g. %1234 becomes %1235).

4.9.10 Symbolic-type commands

**TOP**

This command is used to display the source corresponding to the last instruction to be executed on the current processor. It is the same as typing ‘g’, then ‘i’ (or ‘G’, then RETURN).

**RELOCATE**

This command returns to symbolic mode and performs a symbolic **RELOCATE**. It cannot be used if the processor has been changed at the Monitor page.

**RETRACE**

This command returns to symbolic mode and performs a symbolic **RETRACE**. It cannot be used if the processor has been changed at the Monitor page.
4.10 Symbolic functions

Symbolic debugging allows high level language programs to be debugged from the identifiers used in the source code. Symbolic identifiers are the names given in the program to variables, constants, channels, and functions.

Symbolic functions are invoked using keyboard function keys. Keyboard layouts that show the key bindings for common terminal types can be found in the Delivery Manual that accompanies the release. The symbolic functions are summarized alphabetically below. Each description includes a reference to the page where the command function is described in more detail.

Note: † = Functions only available in interactive mode.

RESUME
This command resumes a process stopped at a breakpoint in a similar manner using the [RESUME] command when in symbolic mode. It is a shorthand equivalent to using the J command and selecting the R option to resume a process stopped at a breakpoint from the monitor page.

HELP
These commands display a summary of the commands available at the Monitor page.

I REFRESH I
This command refreshes the screen.

4.10 Symbolic functions

Locate to the calling function or procedure [page 112].
END OF FILE
Go to the last line in the file [page 113].
CHANGE FILE
Display a different source file [page 113].
CHANNEL
Locate to the process waiting on a channel [page 110].
CONTINUE FROM
† Restart a stopped process from the current line [page 111].
ENTER FILE
Change to an included source file [page 113].
EXIT FILE
Return to the enclosing source file [page 113].
FINISH
Quit the debugger [page 114].
GET ADDRESS
Display the location of a source line in memory [page 113].
4 idebug - network debugger

GOTO LINE
Go to a specific line in the file [page 113].

HELP
Display a summary of commonly used symbolic functions [page 113].

INFO
Display process information (e.g. instruction pointer, process descriptor, process name) [page 110].

INSPECT
Display the type and value of a source code symbol [page 109].

INTERRUPT†
Force the debugger into the Monitor page without stopping the program [page 111].

MODIFY†
Change the value of a variable in memory [page 111].

MONITOR
Change to the monitor page [page 114].

RELOCATE
Locate back to the last location line [page 112].

RESUME†
Resume a process stopped at a breakpoint [page 111].

RETRACE
Undo a BACKTRACE [page 112].

SEARCH
Search for a specified string [page 113].

TOGGLE BREAK†
Set or clear a breakpoint on the current line [page 111].

TOGGLE HEX
Enables/disables hex-oriented display of constants and variables for C and FORTRAN [page 114].

TOP
Locate back to the error or last source code location [page 112].

TOP OF FILE
Go to the first line in the file [page 113].

4.10.1 Symbolic functions

INSPECT
This function displays the value and type of source code symbols. To inspect a symbol, use the cursor keys to position the cursor on the required symbol and press [INSPECT]. If the cursor is not on a valid symbol when [INSPECT] is pressed, a symbol name is prompted for. Type [RETURN] to abort the [INSPECT] operation, or type a name followed by [RETURN]. The case of letters in a variable name is significant — except when debugging...
FORTRAN where case is not significant. Variable names which contain spaces must be entered without the spaces. Specifying an empty expression aborts the INSPECT operation.

The symbol must be in scope from the line to which the debugger last located, which may not be different from the current cursor position. If the symbol is not in scope at that location, or not found at all, one of the following messages is displayed (depending on the language being debugged):

Name 'symbol' not in dynamic scope
Name 'symbol' not found
error: identifier "name" is not in scope
error: identifier "name" not found

Expression language

INSPECT supports an expression language for examining source file symbols. Details of the language and display formats for symbols can be found in the appropriate, language specific, sections below.

CHANNEL

This function ‘jumps’ down a channel if a process is waiting at the other end. This is used in the same way as INSPECT, but positioned on a channel. The debugger locates to the source line corresponding to the waiting process; that process can then be debugged.

The CHANNEL function will jump to other processors along transputer links as long as the program has not been configured to use virtual links (see section 9.4 of the debugging chapter in the User Guide). If a process running on another processor is waiting for communication on a channel the debugger jumps down the link and automatically changes to that processor.

INFO

This function displays the Iptr and Wdesc of the last location, the process name and priority, and the processor number.

If the Wdesc is not in the defined region for a process the message: Undefined process is displayed in place of the process name. For single processor programs that have not been configured there is no defined region and the message: <Stack area unknown> is displayed to reflect this.

If a Wdesc has not been supplied, it is shown as 'invalid'.

72 TDS 367 01 March 1993
4.10.2 Interactive mode functions

The following functions are only available when running in interactive mode.

TOGGLE BREAK

This function toggles a breakpoint on the source line indicated by the cursor and provides information on the breakpoint number (as used by the Monitor page [B] command), whether it was set or cleared, and the line number it is on.

When the source line the cursor is on produces no associated object code the debugger displays an exclamation mark (!) after the line number to indicate that the breakpoint has been toggled on a different line to the one the cursor is on (as shown at the bottom of the display).

RESUME

This function restarts a process stopped at a breakpoint. (To restart a process which has been stopped by one of the debug support functions use [CONTINUE FROM].)

CONTINUE FROM

This function restarts the program from the line indicated by the cursor. [CONTINUE FROM] should only be used to resume a process after it has been stopped by one of the debug support functions. The result of continuing from other points in the code may be unpredictable if there are intervening stack adjustments.

MODIFY

This function changes the value of a variable in transputer memory. For C and FORTRAN, [MODIFY] accepts expressions involving any symbol in scope. To modify a variable place the cursor on the name and press [MODIFY].

Expression language

Variables to be modified can be specified using the [INSPECT] expression language. Details of the syntax can be found in the following language specific sections.

INTERRUPT

This function forces the debugger to enter the Monitor page without stopping the program.
4.10 Symbolic functions

Note: This command does not operate if there are keystrokes waiting before it in the keyboard buffers. It may also fail if the application program is waiting for input from the keyboard.

Note: A side effect of this command is that the debugger suspends iserver communications in order to preserve debugger output to the screen.

4.10.3 Locating functions

The following functions are used to change the debugger's current 'location'. The current location is the point at which the all symbolic functions apply — associated with the location are an instruction pointer value and a workspace address. The initial location will generally be a breakpoint (in interactive mode) or the point where an error occurred (in post-mortem mode).

BACKTRACE

This function locates to the line where a procedure or function was called. If the debugger is already located in the program's topmost procedure, no backtrace is possible.

RETRACE

This function locates back to the previous place where the debugger was located. Repeated use of [RETRACE] reverses the effect of previous [BACKTRACE] operations.

RELOCATE

This function returns the cursor to the last place located to by the debugger. For example, it can be used to return to the original source line of an error after browsing other areas of the code with the cursor keys or the file selection functions.

TOP

This function locates back to the line containing the original breakpoint or error, or to the line located to by the previous use of the monitor page [G] or [O] commands.

4.10.4 Cursor and display control functions

These functions are used to move the cursor around the program and to view other source files.
4 idebug - network debugger

GOTO LINE

This function locates to a particular line in the source file. Specify a line number, or type [RETURN] to abort the operation.

TOP OF FILE

Moves to the start of the current file.

END OF FILE

Moves to the end of the current file.

SEARCH

This function searches forwards in the source file for a specified string. Either specify a search string or press [RETURN] to accept the default, which is the last string specified.

ENTER FILE

Enters an included source file. Position the cursor on the include directive and press [ENTER FILE].

EXIT FILE

Exits from an entered include file.

CHANGE FILE

This function opens a different source file for reading only. No symbolic functions are available, unlike the Monitor page ‘r’ option.

4.10.5 Miscellaneous functions

HELP

This function displays a help screen of the commonly used debugger symbolic functions.

GET ADDRESS

This function displays the address of the transputer code corresponding to the source line where the cursor is currently placed (not necessarily the current ‘location’)

72 TDS 367 01

March 1993
**TOGGLE HEX**

This function turns the display of hexadecimal values of variables on and off. When enabled, the debugger displays hexadecimal as well as decimal values. The default for C and FORTRAN is to display variables in decimal format only.

**MONITOR**

This function switches to the Monitor page environment.

**FINISH**

This function quits the debugger. The Monitor page ‘Q’ command has the same effect. If the command line option ‘XQ’ was used then the debugger will ask for confirmation before quitting.
4.11 INSPECT/MODIFY expression language for C

The expression language for source code symbols (variables, constants, and channels) follows the syntax of the C programming language with some minor modifications.

4.11.1 Syntax not supported

Table 4.6 lists the standard C expression syntax not supported in the debugger expression language.

<table>
<thead>
<tr>
<th>Area of limitation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Casting to pointer types</td>
<td>(char *) ptr</td>
</tr>
<tr>
<td>Calling of functions</td>
<td>sqrt (x)</td>
</tr>
<tr>
<td>Entry of strings</td>

</tr>
</tbody>
</table>

Table 4.7 Limitations to syntax

In addition, the ‘address of’ operator ‘&’ returns an int rather than a pointer to the type.

4.11.2 Extensions to C syntax

Subarrays

The language supports the specification of array subranges for arithmetic data types. Subranges are specified as two array bounds separated by a semicolon. For example: foo[2;4] displays the values of elements foo[2], foo[3] and foo[4].

Note: For arrays and structures the information displayed will normally overwrite part of the screen display. Press any key, when prompted, to restore the display.

Scope resolution operator

The scope resolution operator '::' is available when debugging both C and C++ programs. This allows access to a global identifier which has been hidden by a local declaration, for example:
static int foo = 42;

void example(void) {
    int foo = 321;
    debug_stop(); /* program will stop here */
}

In this example, when the program has stopped at the debug_stop() function, the identifier foo can be inspected and the value 321 (the value that is currently in scope) will be displayed. If ::foo is inspected then the value 42 will be displayed.

Hex constants

The hex constant syntax has been extended to accept a '%' character after the leading ox component of a hex constant. This provides a shorthand mechanism for specifying transputer addresses in a similar manner to that provided in the Monitor page. The '%' character adds INT_MIN (the most negative integer) to the hex constant using modulo arithmetic.

For example, Ox%70 produces the value Ox80000070 on a 32 bit transputer and Ox8070 on a 16 bit transputer.

Address constant indirect

When using [INSPECT] or [MODIFY] a constant expression which has type int or unsigned int may be de-referenced. Normally only pointers may be de-referenced: this addition removes the need to change to the Monitor page to inspect memory locations.

For example, * Ox%0 would display the integer at memory location Ox80000000 on a 32 bit processor.

4.11.3 Automatic expression pickup

When [INSPECT] or [MODIFY] is selected, idebug will automatically 'capture' the identifier which is underneath the cursor (if any). The captured expression can then be modified (using the editing keys described below) before applying the selected option.

In this release the automatic capture is more eager for simple struct or union member expressions which contain only the . and -> operators.

This is best illustrated by example. In the following examples, the cursor is positioned over baz when [INSPECT] or [MODIFY] is selected:
Program text | Expression captured
---|---
baz | baz
baz.ptr | baz.ptr
*(baz).ptr | baz
*baz.ptr | baz.ptr
baz.ptr->ptr | baz.ptr->ptr
baz.foo.ptr | baz.foo.ptr
baz->foo->ptr | baz->foo->ptr
baz[x].ptr | baz

In addition, for those captured expression which match the the program text, the cursor may be positioned anywhere on the expression before selecting `INSPECT` or `MODIFY`.

4.11.4 Editing functions

The following functions are available for the on-screen editing of expressions:

- **START OF LINE**
  - Move the cursor to the beginning of the expression.

- **END OF LINE**
  - Move the cursor to the end of the expression.

- **DELETE LINE**
  - Delete the expression.

- **←**
  - Move the cursor left one character.

- **→**
  - Move the cursor right one character.

- **▲**
  - Replace the current expression with the expression used in the previous `INSPECT` or `MODIFY` operation.

- **DELETE**
  - Delete the character to the left of the cursor.

- **RETURN**
  - Enter the expression for evaluation.

Note:

- `START OF LINE`, `END OF LINE`, `DELETE LINE`, and `DELETE` are mapped by the `ITEM` file to specific keys on the keyboard. Keyboard layouts can be found in the Delivery Manual.

4.11.5 Warnings

When evaluating an expression, checking is performed which may lead to warning messages being produced (e.g. overflow in arithmetic operation, mis-aligned
Such warnings are intended to highlight potential problems and to ensure that a user understands any action `idebug` is taking.

### 4.11.6 Types

C types are interpreted and displayed by the debugger as follows:

ANSI C types are categorized, by the debugger, as shown in table 4.8. These categories define the operations that can be performed on the various types and are also used in error messages when invalid operands are used in expression syntax. For example, arithmetic can be performed on any of the 'scalar' types, but attempting to use a 'derived' type, such as a `struct`, in an expression produces an error message of the form "error: non-scalar left-hand operand..."

<table>
<thead>
<tr>

<td>array, function pointer, <code>struct</code>, <code>union</code></td>
</tr>
</tbody>
</table>

Table 4.8  Type categories in C

**Type compatibility when using `MODIFY`**

Source and destination expressions must be type compatible according to the rules of C. Scalar types are cast automatically into other scalar types but non-scalar expressions must be strictly compatible.

Type conversions, where required, are performed according to normal C promotion rules.

The following examples illustrate the rules governing type compatibility.

Given the following declarations:

```c
int two_d_array[2][10];
int one_d_array[10];
int foo;
char bar;
```

Then the following modifications are permitted:

**Source:** `one_d_array` (array of 10 integers)

**Destination:** `two_d_array[1]` (row of 10 integers)
Source: foo
Destination: bar
(a scalar type: int)

Source: two_d_array[1][2]
Destination: bar
(scalar type: char)
(scalar type: int)

The following modification is not permitted:

Source: two_d_array[1]
Destination: foo
(row of 10 integers)
(scalar type: int)

4.12 Display formats for source code symbols

When displaying an object, idebug will, where possible, also display type information for an object (e.g. unsigned char).

4.12.1 Notation

The debugger uses the following symbols in its display of values:

{} indicates a list of values, or a structure
{}
... indicates a character list of unknown length terminated by a null character

'c' indicates a character

'\HH' indicates a hexadecimal character

" " indicates a character string in an array of known size

" "... indicates a character string of unknown length terminated by a null character

< > indicates the contents of a basic or channel object which is addressed by a pointer (except when the object is volatile)

() provides extra information about an object

In addition, in the descriptions below, the following notation is used:

ddd indicates a (possibly signed) decimal value

0xHHH indicates a hexadecimal value

fff indicates a floating point number of the form: ddd.ddd or ddd.dddEddd
4.12 Display formats for source code symbols

4.12.2 Basic Types

Display formats for basic C types are given in table 4.9. Displays are given in normal decimal format and in hex format (invoked by `TOGGLE HEX`).

<table>
<thead>
<tr>
<th>Type</th>
<th>Hex print off</th>
<th>Hex print on</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>ddd ('c') type</td>
<td>ddd ('\xHH') type</td>
</tr>
<tr>
<td>short</td>
<td>ddd type</td>
<td>0xHHH (ddd) type</td>
</tr>
<tr>
<td>int</td>
<td></td>
<td></td>
</tr>
<tr>
<td>long</td>
<td></td>
<td></td>
</tr>
<tr>
<td>float</td>
<td>fff float</td>
<td>fff (0xHHH) float</td>
</tr>
<tr>
<td>double</td>
<td>fff double</td>
<td>fff (0xHHH) double</td>
</tr>
<tr>
<td>long double</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For char, type is either signed char, or unsigned char.
For integral types, type is either just the type name, or unsigned followed by the type name.

Table 4.9 Basic C types

4.12.3 Default type of “plain” char

By default, the type of a char (known as a “plain” char) typed into idebug is unsigned char. This matches the default implemented by the INMOS C compiler icc. If however, the default type of plain chars has been overridden with the C compiler 'FC' option, it may be necessary to override the default type in idebug by use of a cast. For example:

```
(signed char) 'c'
```

Note that such a cast is only necessary for a plain char entered by hand: idebug will correctly interpret the type of a plain char identifier contained in program code.

4.12.4 Enumerated types

Variables of an enumerated type are displayed as their integer value (in exactly the same manner as an int) followed by the name of the enumeration and the enumeration constant name for the value. If there are multiple enumerated constants that share the same value, a list is formed containing all of the enumeration constant names. `invalid enum constant` is used to indicate when a value is not a member of an enumerated type.

```
integer (enum-tag-name: enum-const-name)
integer (enum-tag-name: {enum-const-name, ...})
integer (enum-tag-name: invalid enum constant)
```

72 TDS 367 01 March 1993
4.12.5 Pointers

Pointers are displayed in one of the following ways:

- $0xHHH$ (null pointer)
- $0xHHH$ (pointer to const volatile)
- $0xHHH$ (pointer to volatile)
- $0xHHH$ (channel pointer to link)
- $0xHHH$ (channel pointer to idebug virtual link link)
- $0xHHH$ (channel pointer to software virtual link link)
- $0xHHH$ (channel pointer to Event in)
- $0xHHH$ (channel pointer)
- $0xHHH$ * (mis-aligned pointer)
- $0xHHH$ < content of basic object >
- $0xHHH$ (pointer)

4.12.6 Function Pointers

If the function pointed to is defined in the current module, then the name of the function is displayed.

- $0xHHH$ (function pointer to "functionname ()")
- $0xHHH$ (cannot find corresponding function)

4.12.7 Structs

Members of structures are described as for other identifiers of the appropriate type. In order to display structures in a readable manner, members which are derived types are not always displayed in as much detail as when the member occurs on its own. To obtain more detail, inspect the member of the structure explicitly.

```c
identifier = {
    member1
    member2
    member3
};
```

For large structures, idebug pages the display and requests confirmation to continue after each page.
4.12.8 Unions

Unions are displayed in the same manner as structs except that a question mark ? appears to the left of each member to indicate that only one member of the union should be selected.

\[
\text{identifier} = \{
    ? \text{ member1 }
    ? \text{ member2 }
    ? \text{ member3 }
\}
\]

4.12.9 Addressof operator &

The result of the addressof operator, & , is automatically printed as both a hex and integer value regardless of the setting of \texttt{TOGGLE HEX}. Note that the result type of addressof is an \texttt{int} rather than a pointer to the type used and is displayed in a similar way:

\[
\text{identifier} = 0xHHH \ (ddd)
\]

4.12.10 Arrays

When displaying arrays, idebug prints the valid range of each dimension (if known) in addition to any type information and the contents of the array. For single dimension arrays containing \textit{arithmetic} types each member of the array is displayed regardless of the size of the array. For large arrays idebug pages the display and requests confirmation to continue after each page. For large arrays, where the full display may be unwieldy, use array subranging to display the area of interest.

Single dimensional arrays of arithmetic types are displayed as:

\[
\text{identifier} = \text{array [0..M] of type } \{\text{list of values}\}
\]

Single dimensional arrays of other types are displayed as:

\[
\text{identifier} = \text{array [0..M] of type}
\]

Multi-dimensional arrays of all types are displayed as:

\[
\text{identifier} = \text{array [0..M][0..N] of type}
\]

Sub ranges of arrays are shown as follows:

\[
\text{identifier}[ddd;ddd] = \text{subarray of type } \{\text{list of values}\}
\]
### 4.12.11 Channels

Channels are displayed with information about the process that is waiting on the channel (or Empty if no is process waiting), in one of the following forms:

- \( \text{identifier} = \text{Channel} <\text{Iptr: address, Wdesc: address (Lo)}> \)
- \( \text{identifier} = \text{Channel} <\text{Iptr: address, Wdesc: address (Hi)}> \)
- \( \text{identifier} = \text{Channel} <\text{Empty}> \)
- \( \text{identifier} = \text{Channel} <\text{Empty (Link link)}> \)
- \( \text{identifier} = \text{Channel} <\text{Empty (Software virtual link link)}> \)

An asterisk * is used to denote an incorrect Iptr or Wdesc which is not in the defined memory map range of the program but is in the defined memory range of the processor.

A double asterisk ** is used to denote an incorrect Iptr or Wdesc which is not in the defined memory map range of the program and not in the defined memory range of the processor.

\( \text{channel (name)} = \text{Channel} <\text{Iptr: addr*, Wdesc: addr**}> \)

### 4.13 Example displays

Tables 4.10 and 4.11 show the display formats for a number of types, using the following source code segment compiled for a 32 bit transputer (for a 16 bit transputer, addresses and integers in hex format would be displayed with 4 hex digits instead of 8). The program containing this code is provided as display.c in the C toolset debugger examples directory.

```c
enum colour { red = 1 };  
struct Many { 
    int     a;  
    double  b; 
};

enum colour  shoe = red;  
struct Many   many = { -42, 2.0 }; 

int   answer = 42;  
char  key = 'A';  
char* string[] = "bye";  
char* ptr = string;  
short iarray[] = { 1, 2, 3, 4 }; 
```

72 TDS 367 01

Table 4.11 Display formats with hex printing on
4.14 INSPECT/MODIFY expression language for OCCAM

The expression language for debugging OCCAM programs is simpler than that provided for C and FORTRAN — only a single identifier name can be entered for inspection and only literal constants can be used as modification values.

4.14.1 Inspecting memory

To inspect the contents of any location in memory, specify an address rather than a symbol name. Type the address as a decimal number, a hexadecimal number (preceded by ‘#’), or the special short form %h...h, which assumes the prefix #8000...

The debugger displays the contents of the word of memory at that address, in both decimal and hexadecimal. For more versatile displays of memory contents, use the Monitor page commands.

4.14.2 Inspecting arrays

If the symbol inspected is an array, elements from the array can be selected using constant integer subscripts enclosed in square brackets (‘[‘ and ’]’); if no subscripts are specified the debugger prompts for them.

For short byte arrays the debugger displays the contents of the array as a string. Otherwise the debugger displays the size and type of the array, and prompts for subscript values. For example:

```
[5][4]INT ARRAY ‘a’, Subscripts ?
```

Press [RETURN] to obtain the address of the array, or enter the required subscripts, which must be in the correct range. The subscripts should be typed either as decimal constant integer values, or as integers separated by commas, for example ‘[3][2]’, or ‘3, 2’. Spaces are ignored.

To simplify access to values indexed by variables (such as ‘a[i]’) an array may be indexed with ‘!’ (e.g. ‘a[!]’) — the ‘!’ character is replaced by the value of the last integer displayed.

Scrolling arrays

As well as simply displaying a single element of an array, the debugger allows an array to be scrolled through one element at a time. In addition, byte arrays can be displayed as a 16 byte ‘segment’ of the array — this segment can be moved up and down like a window into the array contents.

Array scrolling is enabled by adding ‘++’ after the array name when prompted for a symbol name, or after the subscript when responding to the ‘Subscripts ?’ prompt (entering ‘++’ alone in response to the subscript prompt assumes a subscript of zero). The debugger then displays the first array element and then the following prompt on the second line of the screen:

```
Press [UP] or [DOWN] to scroll, any other key to exit :
```
The ▲ and ▼ cursor keys can then be used to scroll through the elements of the array. The debugger will not allow you to scroll past the beginning or end of the array. Pressing any other key will return you to normal symbolic mode.

Byte arrays can be viewed in sixteen character segments by appending a ‘+’ after the array name or subscript. As before, the cursor keys can be used to move the ‘window’ up and down the byte array one character at a time. Using ‘+’ on anything other than a byte array behaves identically to using ‘++’.

### 4.14.3 Type compatibility when using \texttt{MODIFY}

Once a variable is selected the debugger prompts for a new value. The new value should be specified in the expected \texttt{OCCAM} type (as specified within the prompt) although there are a few relaxations to this rule to allow for implicit casts when using the debugger (see below). \texttt{REAL32} and \texttt{REAL64} values must be given in the correct \texttt{OCCAM} format — including a sign for the exponent, if present.

The following \texttt{OCCAM} types may be freely mixed to provide implicit type casts so long as the value is defined within the destination type:

\begin{center}
\begin{tabular}{ll}
\texttt{BOOL} & \texttt{BYTE} \texttt{INT} \texttt{INT16} \texttt{INT32} \texttt{INT64} \\
\end{tabular}
\end{center}

The following are examples of valid modification values:

<table>
<thead>
<tr>
<th>Type</th>
<th>Modify value</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{REAL32}</td>
<td>42 . 0</td>
</tr>
<tr>
<td>\texttt{INT64}</td>
<td>TRUE</td>
</tr>
<tr>
<td>\texttt{INT}</td>
<td>'a'</td>
</tr>
<tr>
<td>\texttt{BOOL}</td>
<td>1</td>
</tr>
<tr>
<td>\texttt{BOOL}</td>
<td>' *#00'</td>
</tr>
<tr>
<td>\texttt{INT16}</td>
<td>$#A0</td>
</tr>
<tr>
<td>\texttt{INT32}</td>
<td>$1A</td>
</tr>
<tr>
<td>\texttt{BYTE}</td>
<td>42</td>
</tr>
</tbody>
</table>

The following are examples of \textit{invalid} modification values:

<table>
<thead>
<tr>
<th>Type</th>
<th>Modify value</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{REAL32}</td>
<td>42</td>
</tr>
<tr>
<td>\texttt{INT64}</td>
<td>2 . 0</td>
</tr>
<tr>
<td>\texttt{BOOL}</td>
<td>' *#02'</td>
</tr>
<tr>
<td>\texttt{INT16}</td>
<td>32768</td>
</tr>
<tr>
<td>\texttt{BYTE}</td>
<td>-1</td>
</tr>
<tr>
<td>\texttt{BYTE}</td>
<td>#100</td>
</tr>
</tbody>
</table>
4.15 Display formats for source code symbols

When displaying an object, idebug will display its type and value, together with its address in memory. If there is too much information to be displayed on one line, it is displayed in two parts. The symbol's name and type is displayed first and then, after a short pause, the value and address.

The display formats for the basic OCCAM types (BOOL, BYTE, INT, INT16, INT32, INT64, REAL32 and REAL64), channels, arrays, and procedures and functions are described below. For protocol names and tags, and timers only the type and name are displayed.

4.15.1 Notation

The debugger uses the following symbols in its display of values:

- 'c' indicates a character
- " " indicates a character string
- ( ) provides extra information about an object
- (at #hhh) shows the memory address of an object

In addition, in the descriptions below, the following notation is used:

- ddd indicates a (possibly signed) decimal value
- #hhh indicates a hexadecimal value
- fff indicates a floating point number of the form: ddd.ddd or ddd.dddEddd
- bbb indicates a boolean value (TRUE or FALSE)

4.15.2 Basic Types

Display formats for the basic OCCAM types are given in table 4.12. When debugging OCCAM programs, the debugger always displays both decimal and hexadecimal values for integer types (regardless of the state invoked by [TOGGLE HEX]).
### Display formats for basic OCCAM types

<table>
<thead>
<tr>
<th>Type</th>
<th>Display</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td><code>\textit{\texttt{name}}</code> has value \texttt{ddd (#hhh, 'c')} (at #hhh) \textit{Note: non–printing characters are displayed as ‘.’}</td>
</tr>
<tr>
<td>BOOL</td>
<td><code>\textit{\texttt{name}}</code> has value \texttt{bbb (at #hhh)}</td>
</tr>
<tr>
<td>INT</td>
<td><code>\textit{\texttt{name}}</code> has value \texttt{ddd (#hhh) (at #hhh)}</td>
</tr>
<tr>
<td>INT16</td>
<td></td>
</tr>
<tr>
<td>INT32</td>
<td></td>
</tr>
<tr>
<td>INT64</td>
<td></td>
</tr>
<tr>
<td>REAL32</td>
<td><code>\textit{\texttt{name}}</code> has value \texttt{fff (#hhh) (at #hhh)}</td>
</tr>
<tr>
<td>REAL64</td>
<td></td>
</tr>
</tbody>
</table>

Table 4.12  Display formats for basic OCCAM types

If a variable is optimized out because it is not used in the program, then the following message is displayed:

\textit{type 'name' was never used and has been optimised out.}

### 4.15.3 Channels

For channels, which are not empty, the \texttt{Iptr} and \texttt{Wdesc} of the process waiting for communication, and its priority, are displayed.

Channels are displayed in one of the following forms:

\begin{itemize}
  \item \texttt{CHAN 'chan' is empty (at \#hhh)}
  \item \texttt{CHAN 'chan' has Iptr: \#hhh and Wdesc: \#hhh (Lo) (at \#hhh)}
  \item \texttt{CHAN 'chan' has Iptr: \#hhh and Wdesc: \#hhh (Hi) (at \#hhh)}
\end{itemize}

An asterisk * is used to denote an incorrect \texttt{Iptr} or \texttt{Wdesc} which is not in the defined memory map range of the program but is in the defined memory range of the processor.

A double asterisk ** is used to denote an incorrect \texttt{Iptr} or \texttt{Wdesc} which is not in the defined memory map range of the program and not in the defined memory range of the processor.

\begin{itemize}
  \item \texttt{CHAN 'chan' has Iptr: \#hhh* and Wdesc: \#hhh (Hi) (at \#hhh**)}
\end{itemize}

If the channel is a hard channel then information about the link (or event channel) that it is mapped onto is also provided. For example:

\texttt{CHAN 'fs' is empty (Link 1 in)}

If the channel is a software virtual link provided by the configurer, then the virtual link number is displayed. However, this does not show whether this is an input or output virtual link. For example:

\texttt{CHAN 'fs' is empty (virtual Link 41 at \#hhh)}
4.15.4 Arrays

If subscripts are specified then the type, value, and address of the array element are displayed as described above.

If no subscripts are given then, for a short BYTE array, the contents are displayed in ASCII. For any other type of array, just the dimensions, type and address of the array are displayed.

4.15.5 Procedures and functions

For procedure or function names, the entry address, and nested workspace and vectorspace requirements are displayed (no address is displayed for library names):

PROC 'name' at #hhh, uses ddd WS and ddd VS slots

FUNCTION 'name' at #hhh, uses ddd WS and ddd VS slots

4.16 Example displays

Table 4.13 shows the display formats for a number of types, using the following source code segment compiled for a 32 bit transputer (for a 16 bit transputer, addresses and integers in hex format would be displayed with 4 hex digits instead of 8).
-- Debugger example: display.occm
-- Example ofoccam display types within idebug.
-- Note: This example uses the PAR construct in an
-- inefficient manner for illustrative purposes only.
--
#INCLUDE "hostio.inc"
#INCLUDE "linkaddr.inc"
#USE "hostio.lib"
#USE "debug.lib"

PROC example (CHAN OF SP fs, ts, []INT free.memory)
  VAL name IS "occam example":

  CHAN OF INT ca, cb:
  PLACE ca AT event.in:
  BOOL bool:
  BYTE byte:
  INT int:

Table 4.13 occam display formats
4.17 Error messages

This section lists error messages generated by idebug. Other messages not in this list may be generated by corrupt files and by files not created by the toolset.

4.17.1 Out of memory errors

If the debugger runs out of memory when trying to read in information and the offending code module cannot be reduced in size, the amount of memory available to the debugger may be increased by increasing the size of the memory on the transputer the debugger is running on and updating IDEBUGSIZE accordingly.

4.17.2 If the debugger hangs

If the debugger starts up but then hangs with the message:

    Loading network...

one of the following errors may have occurred:

1. The network connectivity is not correctly described in the configuration description, for example, a link is not connected to a processor, or the type of a processor has been specified incorrectly.

   Network connectivity on a board can be checked by running a check or worm program, such as the ispy program supplied with the support software for some INMOS iQ systems products. These products are available separately from your local INMOS distributor.

2. You have set IDEBUGSIZE to be larger than the memory on the root processor (where the debugger is running).

   Change IDEBUGSIZE to reflect the correct root processor memory size.

4.17.3 Error message list

"filename" not compiled with full symbolic debug information

   The object code module does not contain sufficient debug information for the debugger to locate to its corresponding source code (i.e. it contains minimal debug information). Recompile the module and rebuild the program in order to debug it symbolically.

Already located – No process is waiting at the other end of this link

   An attempt to jump down a hard channel (link) has failed because there is no process waiting at the other end.
4.17 Error messages

Attempted read outside Parameter block
Attempted write outside Parameter block

The configuration system has become corrupted. Check hardware using a memory check program such as ispy. (The ispy program is supplied as part of the board support software for INMOS iq systems products. These products are available separately from your local INMOS distributor.)

Can only specify a transputer type if bootable is for a class

Cannot specify a transputer type for configured bootable files

You have tried to specify a processor type when the bootable file is already for a specific processor type.

Cannot create network dump – reason

Creation of a network dump file is not permitted on a program that is, or has been, interactively debugged. reason can be either of the following:

1 when in Interactive mode
2 when in Postmortem Interactive mode
3 Already reading one

Cannot debug boot from ROM run in ROM file "filename"

You may only debug boot from ROM run in RAM programs with idebug.

Cannot find this line's location

Either of the following has occurred:

1 You have moved the cursor beyond the end of the current source file for which there is no executable code.
2 The compiler has optimized the executable code out.

Cannot locate beyond Freespace area

The address specified is not within the memory map range of the processor.

Cannot locate to area (lpotr: #address)

The address specified is not within the code area for the program on the processor. area can be any of the following:

Reserved transputer memory
Runtime kernel
Reserved memory
Configuration code area
Stack area
Vectorspace area
Static area
Heap area
Freespace area

Cannot open "filename"

Either the file does not exist or it is not on the ISEARCH path (note that by default this includes the current directory). The ilist tool can be used to confirm this.

Note: if the file name is vrdebXX.txt (or something similar), where XX is a sequence of digits, then you are probably trying to locate to one of the configurer's software virtual link processes. Use the Z command to display processes waiting on the software virtual links.

Cannot read processor number (Txxx)

The debugger cannot communicate with that processor. Any of the following errors may have occurred:

1  The root processor's core dump has been incorrectly specified.
2  The debugger has failed to analyze the network correctly. Either you have failed to specify the 'A' option or the system control signals are wired incorrectly.
3  The network does not match that specified in the configuration file. Check network connectivity using a check program such as ispy. (The ispy program is supplied as part of the board support software for INMOS iq systems products. These products are available separately from your local INMOS distributor.)

Cannot run application – the program has crashed!

Use the Y (Enter post-mortem debugging) Monitor page command to post-mortem debug the (now defunct) breakpoint session.

Channel is invalid

The channel does not point to a known process executing on the processor.

Configuration info inconsistent with linked unit

You have probably relinked a component of a program and forgotten to reconfigure it.
4.17 Error messages

Configured for post-mortem debugging only

You have explicitly disabled interactive debugging (using configurer or collector options).

Debug info too large (reason)

The debugging information for a particular compilation module is too large for the debugger. Either reduce the size of the offending module or increase the size of memory on the processor where the debugger is running (see section 4.17.1 on how to overcome this).

reason can be any of the following:

ix.tags is full
ws.array is full
name table is full

Debugger incompatible configuration file "filename"

You have configured your program without specifying the debugger compatible option ('G' option) to the configurer, icconf.

For mixed language programs configured with the occam toolset configurer occonf, the error may be that you have configured your program with the configurer 'RE' option to enable memory layout re-ordering.

File has changed since configuration "filename"

You should rebuild the program again.

FILE IS TOO BIG – truncated

The debugger buffer capacity has been exceeded. The buffer contains as much of the file as could be read before the capacity was exceeded (see section 4.17.1).

Illegal virtual channel address

The channel has been (possibly incorrectly) tagged as virtual but does not point to a valid software virtual channel (as defined by the debugging kernel or the configurer). This is caused by a channel that has become corrupted (normally by overwriting the location of the channel). You should ensure that no compiler checks have been disabled to prevent accidental corruption.

Incompatible debugger modes: message

Mutually incompatible options have been specified on the command line.

Interactive debugging has been disabled

The module has been linked with the linker 'y' option to disable breakpoint (interactive) debugging. Rebuild your program without disabling interactive debugging and retry.
ITERM error on line linenumber, message

The debugger has detected a syntax error in the ITERM file. message describes the error.

Name symbol is not in dynamic scope

The symbol symbol exists in the module, but is not in scope from where the debugger last located to. In order to inspect the symbol you must locate to a new position where the symbol is in scope.

Not a (compatible) bootable file "filename"

The file is either a non-bootable file or a pre-product release bootable file. Use i.list to determine the contents of the file if in doubt.

Not enough free memory for the debugger

You have either not set the environment variable IDEBUGSIZE or you have set it to be too small (it should be > 400K). Change the variable to reflect the memory size of the root processor.

Not on a valid INCLUDE line

You may only use ENTER FILE when the cursor is on a line with an include directive.

Only debugging tools and cursor keys are available

You have pressed a key which is not defined.

Option must be followed by a link number (0 – 3)

Command line options ‘B’, ‘M’, and ‘T’ require a link number in the range 0 to 3.

Option must be followed by a valid processor type (eg. T425)

The processor type supplied is not recognized by the debugger.

(Probe Go) : Processor number – Cannot contact

The debugger is unable to communicate with processor number. The processor type specified in the configuration (or to the debugger via the ‘C’ option) does not match that found. Check the network using a program such as ispy in order to determine the correct processor type.

(Probe Go) : Processor number – Expected processor type Txxx, found Txxx

The processor type specified in the configuration (or to the debugger via the ‘C’ option) does not match that found. Check the configuration descrip-
tion and the network (using a program such as ispy) in order to determine the correct processor type.

(Probe Resume) : Processor number — Invalid Breakpoint

The debugger has stopped at a breakpoint which it did not place in the code. If you wish to continue executing the program set a breakpoint at the same address and retry the command.

Processor number : insufficient memory, require at least number bytes

The memory requirement of the processor as specified to the configurer, the collector, or in IBOARDSIZE (as appropriate) is too small. (Note that the value displayed may include memory for some configuration code that is reclaimed when program starts executing.)

This may also be caused by the debugging Runtime kernel using an extra 11—15K of memory.

Processor type must be a 32 bit processor (eg. T425)

You must specify a 32 bit processor type because processor classes are for 32 bit processors only.

Processor type must be not abbreviated

You must specify specific processor types rather than abbreviated types (e.g. T425 rather than T5) because some abbreviated types cover more than one specific type.

READ ERROR — truncated

The debugger could not read all of the file. The buffer contains as much of the file as could be read (see section 4.17.1 on how to overcome this).

Runtime kernel is not present (or has been overwritten)

Either the runtime kernel has been corrupted or you are trying to post-mortem a breakpoint session that didn’t occur.

There is no enclosing INCLUDE

You have attempted to use EXITFILE when not located in a nested include file.

There are no processes waiting at either end of this link

An attempt to jump down a hard channel (link) has failed because there are no processes waiting at either end.

This transputer link is connected to the host

The link specified in the ‘B’, ‘M’, or ‘T’ command line option is the communication link from the debugger to the host and is not connected to the network.
Too many processes declared at configuration level (number)
Too many processes used at configuration level (number)

The debugger requires more memory in order to operate on this many processes (see section 4.17.1 on how to overcome this).

Too many processors – There is only enough room for (number)

The debugger requires more memory in order to operate on this many processors (see section 4.17.1 on how to overcome this).

Unable to find any low priority entrypoints on any processor
Unable to find any low priority entrypoints on this processor
Unable to find any low priority main () on this processor

The processes you have requested the debugger to set breakpoints in are all at high priority on processors with no hardware breakpoint support.

Unable to read environment variable ITERM

There is no translation for the ITERM environment variable which defines the screen and keyboard format.

Unable to toggle a breakpoint on this line

The breakpoint cannot be set or cleared on this source line. Either:

1. The current file contains no executable code, or
2. Executable code is contained in an include file and the debugger cannot determine whether you mean to toggle the breakpoint in that file or in the current file.

Move to the line where you really want to toggle the breakpoint and retry the command.

Unknown core dump format "filename"

The network dump file is in the wrong format or the wrong file has been specified. You can use ilist to determine the format of the file.

Wdesc is invalid – message

The Wdesc supplied is invalid: this may be deliberate because it is unknown. If you supplied it from the Monitor page environment, retry the command with a valid Wdesc.

message can be one of:

cannot inspect variables
cannot modify variables
cannot backtrace
cannot auto backtrace out of library

Wrong number of processors in network dump file filename

The number of processors does not correspond to the current program. The wrong network dump file may have been specified.

You cannot backtrace from here (to configuration code)

This normally occurs when you try to backtrace from the program's topmost procedure into the bootstrap routine which is not supported symbolically by the debugger (i.e. the configuration code area).

You cannot backtrace from here (to Iptr: #nnn, Wdesc: #mmm)

An attempt to backtrace from a procedure or function has failed because the resultant process details are invalid (e.g. Iptr is not in the Code area), or you are trying to locate to a software virtual link router process.

The Iptr and Wdesc shown are those of the invalid process which supposedly called the current procedure or function.

If this error occurs, you should use [INFO] before backtracing to check that the current process details are valid (they are normally only invalid when incorrect process details have been specified with the Monitor page '0' command). Corruption of the stack (workspace) is another possible cause of this error; to prevent accidental corruption you should ensure that no compiler checks have been disabled.

This error can also occur if you try to locate to a process which implements the software virtual links. This can be checked by using the [V] command to search for a process with a Code area which contains the displayed Iptr and a stack area which contains the displayed Wdesc. If the name of the process is "%ROUTER[n]" then it is a software virtual link process which can not be located to.

You have changed file, so you can't use this key

There are certain symbolic features that cannot be used if you have changed to another source file. Either use [RELOCATE], or relocate to the original file using the Monitor page [F] (Select file) command, before retrying the command.

You must specify a filename

The command line syntax requires a filename.
You must specify a transputer type (bootable is for a TA class)
You must specify a transputer type (bootable is for a TB class)

The program you are trying to debug is for a transputer class (either TA or TB); the debugger needs to know the actual processor type (e.g. T425).

You should retry using the debugger with the command line 'C' option to specify the appropriate processor type.

You must specify the application boardsize in IBOARDSIZE to be <= #10000

On a T2 the maximum memory size is 64K (#10000).
This chapter describes the memory dumper tool *idump* that dumps the contents of the root processor's memory to disk. It is used to enable the debugging of code running on the root transputer.

### 5.1 Introduction

The memory dumper allows programs that use the root transputer to be debugged in the normal way using the debugger tool *idebug*. It is required because *idebug* runs on the root transputer and overwrites all code and code in its memory. *idump* saves the contents of the root transputer to a disk file in a format that can be read by the debugger. Information contained in the file allows the debugger to analyze data in the root transputer in the same manner as other transputers on the network.

When *idump* is invoked it calls the server with the 'SA' option so that the space occupied by the dumper program is saved before it is loaded onto the transputer.

### 5.2 Running the memory dumper

To invoke the *idump* tool, use the following command line:

```plaintext
idump filename memorysize [{ startoffset length }]
```

where: *filename* is the name of the dump file to be created.

*memorysize* is the number of bytes, starting at the bottom of memory, to be written to the file.

*startoffset* is an offset in bytes from the start of memory.

*length* is the amount of memory in bytes, starting at *startoffset*, to be dumped in addition to *memorysize*.

All parameters can be expressed in either decimal or in hexadecimal format. Hexadecimal numbers must be preceded by the hash character '#' or the dollar sign '$'.

The memory dump file stores the contents of the transputer's registers and the first *memorysize* bytes of memory. The file is given the .dmp extension. After the dump has been performed *idump* remains resident on the transputer board ready to load the debugger.
memorysize must be large enough to contain the complete program with its workspace and vectorspace. If the program to be dumped uses the free memory buffer, the whole of the transputer board’s memory should be dumped.

Further portions of memory can be dumped by specifying the start of the segment of memory to be dumped and the number of bytes, using pairs of startoffset length parameters. The start address is given by startoffset and the number of bytes by length. The overall size of the memory dump file is given by the amount of memory saved plus around 500 bytes for the register contents.

5.2.1 Example of use

Assuming a value of 100K for IBOARDSIZE:

   idump core 102400

This command writes the contents of the root transputer’s memory to the file core.dmp. The .dmp extension is added by default because the filename is specified with no extension.

5.3 Error messages

Badly formed command line

   Command line error. The command syntax requires a file name followed by the number of bytes of memory to dump. Check the syntax of the command and retry.

Cannot open file

   File system error. The memory dump file could not be opened on the host system.

Cannot write file

   File system error. The memory dump file could not be written to the host system.

You must tell the server to peek the transputer

   idump has been invoked by calling the host file server with the incorrect option. This error can only occur if the tool is not invoked with the supplied driver file.
This chapter describes the memory configuration tool \texttt{iemit}. This tool can be used interactively to explore the effects of changes in the external memory interface parameters of certain 32 bit transputers. The tool can also be used in batch mode to create ASCII or PostScript files. The tool produces a memory configuration file which may be included as an input file to \texttt{ieprom} and blown into EPROM along with a ROM-bootable application file.

The chapter describes how to use \texttt{iemit} and outlines its capabilities. Example displays are provided, followed by a list of error messages which the tool may generate. The format of the memory configuration file is described and an example is given. Note: memory configuration files are simple text files which may be created manually using a standard text editor or generated by using \texttt{iemit}.

### 6.1 Introduction

The IMS T400, T414, T425, T426, T800 and T805 transputers have a configurable external memory interface (EMI) which allows a variety of types of memory device to be connected using few extra components.

For these transputers, the interface configuration may be selected by one of two mechanisms. The user may select one of the 17 standard memory configurations (13 for the T414) or a customized memory configuration may be loaded from a ROM or PAL on reset.

Both methods of memory configuration are available when booting from ROM or from link. If the transputer is being booted from ROM, a customized memory configuration may be added to the ROM or a standard configuration may be used. If the transputer is booted from link a standard configuration may be used at no extra cost, or a dedicated ROM or PAL may be added for a customized configuration.

In order to generate a customized configuration the user may create a memory configuration file, describing the memory configuration and have this blown into an EPROM. The configuration chosen is made known to the transputer by simple board level connections which are detected by the transputer on reset. If a standard configuration is required the MemConf\texttt{ig} pin is connected to the appropriate address pin. For example, standard configuration 7 is selected via address pin MemAD7. If a customized configuration is required the MemConf\texttt{ig} pin is connected through an inverter to the appropriate data line, usually this is MemnotWrDO. Note: when \texttt{iemit} is used to generate the memory configuration,
the MemnotWrD0 pin must be used. For further details see *The transputer databook*.

The external memory interface configuration tool *iemit* produces timing diagrams for potential configurations of the memory interface and warns of possible errors in the design. It indicates whether one of the preset configurations that are available would be suitable, or whether it would be necessary to use an externally programmed configuration.

**Note:** That it is assumed that readers creating memory configuration files are familiar with the memory interface of the processor that they are using. The stages in designing a memory interface, including examples, are described in chapter 2 of *The transputer applications notebook - Systems and performance*. Further information may also be found in *The transputer databook*.

### 6.2 Running *iemit*

The *iemit* tool can be invoked by the following command line:

```
   iemit options
```

where: *options* is a list of options given in Table 6.1.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Produce ASCII output file.</td>
</tr>
<tr>
<td>E</td>
<td>Invoke interactive mode.</td>
</tr>
<tr>
<td>F filename</td>
<td>Specify input memory configuration file.</td>
</tr>
<tr>
<td>I</td>
<td>Select verbose mode. In this mode the user will receive status information about what the tool is doing during operation for example, reading or writing to a file.</td>
</tr>
<tr>
<td>O filename</td>
<td>Specify output filename.</td>
</tr>
<tr>
<td>P</td>
<td>Produce PostScript output file.</td>
</tr>
</tbody>
</table>

Table 6.1 *iemit* command line options

**Note:** that if option 'E' is selected i.e. interactive mode, then no other options may be specified on the command line.
The operation of `iemit` in terms of standard file extensions is shown below:

![Diagram showing file extensions](image)

**Examples of use**

`iemit` may be invoked in interactive mode by using one of the following commands:

```
iemit -e          (UNIX based toolsets)
iemit /e           (MS-DOS and VMS based toolsets)
```

Output files in ASCII or PostScript may be specified by command options from within interactive mode; alternatively `iemit` may be invoked in batch mode, to create an output file in one of these formats.

When the tool is invoked in batch mode to produce an output file in either ASCII or PostScript format, then an input file must be supplied using the `F` option. It is also mandatory to specify either the `A` or `P` option. If the `O` parameter is not supplied then an output filename will be constructed, from the input filename, with an extension of `.`ps` for a PostScript output, or `.`asc` for an ASCII output.

**Example:**

The following commands cause `iemit` to produce an output file in PostScript format. The tool is invoked in verbose mode.

**UNIX based toolsets:**

```
iemit -i -p -f memconfig.mem -o waveform.ps
```

**MS-DOS and VMS based toolsets:**

```
iemit /i /p /f memconfig.mem /o waveform.ps
```

**Note:** `iemit` will make use of the `ITERM` host environment variable, if it is available, otherwise it will use defaults.
6.3 Output files

Two different types of output may be produced by iemit, these are listed below:

- A memory configuration file suitable for including as an input file to the ieprom tool.
- An output file in either ASCII or Postscript format, suitable for inclusion in documentation.

The tool may be used interactively to produce a memory configuration file in text format. This file may then be used as an input file to the ieprom tool, thus enabling the memory configuration to be stored on ROM. iemit is capable of saving and reloading configurations to allow for design over an extended period and for comparison of different configurations. The memory configuration file is described and an example is given in section 6.6.

Additionally iemit may be used to produce an output file which is either a plain ASCII file containing timing data or a file in PostScript format containing waveform diagrams. These formats were chosen so that the results of the program could be easily included in reports or other documentation.

6.4 Interactive operation

When iemit is invoked in interactive mode the program will start up with the default standard configuration 31.

The tool’s user interface is presented as a number of display pages showing timing data. The displays may be updated by changing the timing parameters, which are accessed from page 1. All inputs are executed immediately so that the user can see the effect on any of the displays. As each page is shown, the user has the option of selecting another page for display by keying in its number. The current configuration may be saved at any time to a specified output file.

The information displayed and options available on each page are described below.

6.4.1 Page 0

This page acts as an index to the others. It shows the title of each page and allows one of them to be selected. An option is provided to enable an input file to initialize the memory configuration. Other options enable the user to selectively generate output files. Options are listed in table 6.2 and an example of the display page is given in figure 6.1.

The user enters an option code followed by the [RETURN] key. If a file option is specified the user will be prompted for a filename. Note: file extensions should be specified, there are no defaults.
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 to 6</td>
<td>Selects the page to be displayed.</td>
</tr>
<tr>
<td>Q</td>
<td>Quit - selection of this option exits the program.</td>
</tr>
<tr>
<td>L</td>
<td>Load previously saved configuration. A filename is prompted for, and the configuration saved in that file is read in and the display data is updated. The program expects a memory configuration file. If loading does not succeed because the file has a bad format, the current configuration is reset to standard configuration 31. If loading fails because the file could not be found or could not be opened for reading, the load is abandoned without losing the current configuration.</td>
</tr>
<tr>
<td>S</td>
<td>Save configuration to a file. The program prompts for the name of a file to which the data will be written, by convention the extension <code>.mem</code> should be used. Output is a memory configuration file. An error is reported if the data could not be saved. The saved file is given comments in its header indicating that it was created by the <code>iemit</code> program.</td>
</tr>
<tr>
<td>A</td>
<td>Output pages in ASCII format to a file. The program prompts for the name of a file to which the data will be written. Output is in plain ASCII format with a form feed (FF) character after each page. It includes full timing information and a representation of the timing diagrams for read and write cycles. An error is reported if the output could not be written.</td>
</tr>
<tr>
<td>P</td>
<td>Generate PostScript file. The program prompts for a filename. The program writes to the file a program in the PostScript page description language to draw the timing diagrams for the chosen memory interface configuration. The waveforms shown are the same as those which can be seen by selecting pages 4 and 5. The file produced fully conforms to the PostScript structuring conventions, allowing it to be processed by other programs. The diagram is designed to fit lengthways on an A4 page, and is suitable for inclusion in technical notes and reports. The file can be sent directly to an Apple LaserWriter or other PostScript output device.</td>
</tr>
</tbody>
</table>

<tr>
<td></td>
<td>T425-25 T805-25</td>
</tr>
<tr>
<td></td>
<td>T425-30 T805-30</td>
</tr>
<tr>
<td><strong>Tstates T1-T6</strong></td>
<td>The length of each Tstate T1 to T6, is entered as a number of Tm periods between 1 and 4. (2 Tm periods = 1 clock cycle).</td>
</tr>
<tr>
<td><strong>Programmable Strobes S0-S4</strong></td>
<td>The programmed durations of the strobes notMemS0 to ()notMemS4(). The strobes each have two names which can be altered. One which can be up to 9 characters in length, and one consisting of just one character. There should be no embedded spaces in the long names. The short names are used in the timing information on pages 2 and 3, while the long names are used to label the waveforms on pages 4 and 5, and in the PostScript output. The signal names are initialized to sensible defaults. Note: that S0 is a fixed strobe, so its duration cannot be changed. The duration of a strobe can be 0 to 31 Tm periods. If the value for S1 is set to zero, then notMemS1 stays high throughout the cycle; if the value for S2, S3 or S4 is set to zero, then the strobe is low for the duration of the cycle.</td>
</tr>
<tr>
<td><strong>Read strobe name</strong></td>
<td>The names for the read strobe notMemRd can be altered.</td>
</tr>
<tr>
<td><strong>Write strobe name</strong></td>
<td>The names for the write strobe notMemWrB can be altered. Note that because the four byte write strobes have the same timing, only one is considered.</td>
</tr>
<tr>
<td><strong>Refresh period</strong></td>
<td>The refresh period is given as a number of ClockIn periods (18, 36, 54, or 72) or as Refresh Off if zero is selected.</td>
</tr>
</tbody>
</table>

Table 6.4 iemit page 1 parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write mode</td>
<td>The write mode can be set to Early or Late to suit the type of memory being used.</td>
</tr>
<tr>
<td>Wait connection</td>
<td>The MemWait input may be connected to one of the strobes S2, S3, S4 by entering 'S2', 'S3' or 'S4' respectively. Alternatively, by specifying a number in the range 1 to 60 MemWait may be connected to a simulated external wait state generator. This causes MemWait to be held high then to become inactive (low) a set number of Tm periods after the start of T2. Note: that this mode is not supported directly by the T414; in a final design, a circuit would have to be built to perform this function. If the current connection of MemWait causes the signal to become inactive just as ProcClockOut is falling during T4, a warning is given that there is a hazard of a wait race condition. This is because MemWait is sampled on the falling edge of ProcClockOut—and if the signal is changing while being sampled, the result is undefined.</td>
</tr>
<tr>
<td>EMI clock period Tm</td>
<td>The value of Tm for a clockIn frequency of 5MHz. This is computed from the other parameters and displayed.</td>
</tr>
<tr>
<td>Wait states</td>
<td>The number of wait states in the current configuration. This is computed from the other parameters and displayed.</td>
</tr>
<tr>
<td>Standard configuration</td>
<td>The parameters can all be reset to those for one of the built in configurations. There are 13 standard configurations available for the T414, valid configuration numbers being 0 to 11 and 31. For the T400, T425, T800 and the T805 there are 17 standard configurations available, valid configuration numbers being 0 to 15 and 31. If the user selects, for a T414, one of the four configurations which are not available, a message will be displayed indicating that this configuration may not be hardwired on a T414. If the currently set configuration happens to correspond exactly to one of the preset configurations, the tool reports the fact.</td>
</tr>
</tbody>
</table>

Table 6.7 DRAM timing parameters

6.4.5 Page 4

This page shows graphically the timing for a memory read cycle. An example of the display page is given in figure 6.5.

The Tstates and strobes are labelled, and bus activity is shown. The point where data are latched into the processor is also indicated.

At the top of the page is displayed the processor clock and the Tstates, a number indicating the Tstate, 'W' indicating a wait state, and 'E' indicating a state that is inserted to ensure that T1 starts on a rising edge of the processor clock.
Below this are displayed the waveforms of the programmable strobes and the read, write and address/data strobes. Each of these strobes is labelled with the corresponding label parameter.

The point at which the read data is latched is indicated by a "A" beneath the read cycle address/data strobe.

![Waveform Diagram]

**Figure 6.5 Example iemit display page 4**

The MemWait waveform shows the input to the MemWait pin. If the wait input is a number then it goes low \( n \) \( T_m \) periods after the end of \( T_1 \) and high again at the end of \( T_6 \), if the wait input is connected to a strobe it goes low and then high when that strobe does so.

If the cycle is too long to fit horizontally on the screen, it may be scrolled left and right using the \([L]\) and \([R]\) keys. The displayed area moves by about 15 characters each time these are used.

### 6.4.6 Page 5

Page 5 shows the waveforms for a memory write cycle. The display is similar to that of page 4, indeed the read and write cycle diagrams are combined when the PostScript output is produced.

Scrolling the display to the left or right is done in the same way as for page 4.

An example of the display page is given in figure 6.6.

**Figure 6.6 Example iemit display page 5**

### 6.4.7 Page 6

This page gives a configuration table for the current configuration. This is a listing of the data which have to be placed in a ROM situated at the top of the transputer's memory map in order to achieve the desired configuration. The table consists of 36 words of data, but only the least significant bit in each is used. The address and contents are given for each location. Note: when iemit is used to generate the memory configuration, the Memconfig pin must be connected to MemnotWrD0.

An example of the display page is given in figure 6.7.

Note: that if page 1 indicates that the configuration is one of the transputer's preset ones, there will be no need for a ROM; configuration can be achieved by connecting the MemConfig pin of the device to one of the address/data lines.
configuration cannot be hardwired on a T414

The transputers which have a configurable memory interface all have (with the exception of the T414) 17 standard memory configurations available
to them. The T414 only has a choice of 13 standard configurations. If the
standard configurations 12, 13, 14 or 15 are selected for a T414 the above
warning message will be displayed against the selection on page 1.

Unable to open configuration file 'filename'

This can occur when attempting to load a memory configuration file and
indicates that the tool cannot find the specified input file. Check the spelling
of the filename and/or that the file is present.

Command line parsing error

An option has been specified that the tool does not recognize.

No input file specified

This indicates that when trying to invoke the tool to produce an output file,
the user has not specified a memory configuration file to use as input.

One and only one of options A or P must be specified

This indicates that when trying to produce an output file, the user has not
specified whether the output is to be in ASCII or PostScript format.

Unable to open output file 'filename'

An output filename has been specified incorrectly. Check the format of the
filename.

6.6 Memory configuration file

Memory configuration files are text files which may be generated by a standard text
editor or by using the memory interface configuration tool iemit, see section 6.2.

By convention memory configuration files have the file extension .mem. The file
consists of a sequence of statements and comments. The following are consid-
ered to be comments:

- Blank lines
- Any line whose first significant characters are ‘--’
- Any portion of a line following ‘--’.

Comments are ignored by the ieprom and iemit tools. Statements are all other
lines within the file; they may be interspersed with comments.

Individual statements are constructed of the statement and an associated param-
eter. These must be separated by at least one space or tab but extra spaces may
be inserted before, between, or after them for aesthetic purposes. An example memory configuration file is shown in figure 6.8.

Table 6.8 Memory Configuration file statements
This chapter describes the EPROM hex tool `ieprom`. This tool is used to convert a ROM-bootable file into one or more files suitable for programming an EPROM.

The chapter describes how to invoke `ieprom` and gives details of the command line syntax. It describes the control file which the tool accepts as input and provides background information on the layout of the code in the EPROM. A description of the various file formats which may be output by the tool is given, including block mode where the output is split up over a number of files. The chapter ends with a list of error messages which may be generated by the tool.

### 7.1 Introduction

The INMOS EPROM software is designed so that programs which have been developed and tested as boot-from-link programs, using the INMOS toolset may be placed in ROM with only minor modification (see below).

This has the advantages that an application need not be committed to ROM until it is fully debugged and the actual production of the ROMs can be done relatively late in the development cycle without the fear of introducing new problems.

If a network of transputers is being used, only the root transputer needs to be booted from ROM; once this has been booted it will boot its neighbors by link.

Figure 7.1 shows how a network of five transputers would be loaded from a ROM accessed by the root transputer.

![Diagram of network booting from ROM](image)

**Figure 7.1** Loading a network from ROM
Some 32 bit transputers have a configurable external memory interface. For these transputers a memory configuration file may be created and put into ROM together with the application. A description of memory configuration files and how to create them is given in Chapter 6.

7.2 Prerequisites to using the ieprom tool

For an application file to be suitable for programming into ROM it must have been configured to be booted from ROM rather than booted from link. This selection is made by specifying the appropriate command line option when using the configurer and collector tools (see the relevant chapters of this manual). It is also essential that all C and FORTRAN programs, including those targeted at a single processor, are configured. C and FORTRAN programs prepared with the icollect 'T' option are not in a format suitable for ieprom.

7.3 Running ieprom

ieprom takes as input a control file and outputs one or more files which may be put into ROM by an EPROM programmer.

The control file, in text format, specifies the root transputer type, the name of the bootable file containing the application, the memory configuration file (if one is being used), the amount of space available in the EPROM, and the format that the output is to take. Available output formats are: binary, hex dump, Intel, Extended Intel, or Motorola S-Record format.

The ieprom tool is invoked by the following command line:

```
>>> ieprom filename {options}
```

where: `filename` is the name of the control file.

`options` is a list of options from Table 7.1.

| Options must be preceded by `-' for UNIX-based toolsets and `/` for MS-DOS and VMS based toolsets. |
| Options may be entered in upper or lower case and can be given in any order. |
| Options must be separated by spaces. |

If no arguments are given on the command line a help page is displayed giving the command syntax.

72 TDS 367 01 March 1993
Table 7.1 ieprom command line options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Selects verbose mode. In this mode the user will receive status information about what the tool is doing during its operation, for example reading or writing to a file.</td>
</tr>
<tr>
<td>R</td>
<td>Directs ieprom to display the absolute address of the code reference point. This address can be used to locate within the memory map created by the icollect ‘P’ option.</td>
</tr>
</tbody>
</table>

The operation of ieprom in terms of standard file extensions is shown below.

7.3.1 Examples of use

ieeprom may be invoked in verbose mode by using one of the following commands:

```
ieeprom -i mycontrol.epr  # (UNIX based toolsets)
ieeprom /i mycontrol.epr  # (MS-DOS and VMS based toolsets)
```

7.4 ieprom control file

The control file is a standard text file, prepared with an editor; it consists of comments and statements. A comment is any blank line or any text following the comment marker ‘--’. Comments are ignored by the ieprom tool.

Statements are all other lines within the file. They may be in any order, except that the four statements defining a block must immediately follow the statement ‘output.block’ (see table 7.3). Statements may be interspersed with comments.

Individual statements are constructed of a keyword and an associated parameter. These must be separated by at least one space or tab but extra spaces may be inserted before, between, or after them for aesthetic purposes. The statements are listed, along with their parameters, in tables 7.2 to 7.4.

Examples of control file contents are given in section 7.8.
The statements in table 7.2 are used to specify the contents of the EPROM: the processor type, the source of the data (code and memory configuration) to be placed in the EPROM, and the total size of EPROM memory.

<table>
<thead>
<tr>

Table 7.4  Output block specification

7.5 What goes into the EPROM

This section describes the contents of the EPROM, the reasons behind the code layout and the function of those components inserted by ieprom.

The contents of the EPROM includes the bootable file, traceback data and jump instructions to enable the processor to find the start of the bootable file. Should the user define the memory configuration this information will also be placed in the EPROM. The general layout of the code in the EPROM is shown in figure 7.2.

7.5.1 Memory configuration data

Memory configuration data, when present, is placed immediately below the top word of the EPROM. The top word holds the first instructions to be executed if the transputer is booting from ROM.

If the processor has a configurable memory interface it will scan the memory configuration data held on the EPROM, before executing the first instructions. If a standard memory configuration is being used there should be no memory configuration data present and the processor will ignore this section of the EPROM.
### 7.5.2 Parity registers

The T426 has the ParityErrorReg and ParityErrorAddressReg mapped into the two words immediately below the memory configuration data (addresses #7FFFFFF64 and #7FFFFFF68). The EPROM tool needs to know that it must avoid these addresses on the T426 and so the processor type must be given explicitly in the `root.processor.type` statement.

### 7.5.3 Jump instructions

The first instruction executed by the processor when booting from EPROM, is located at *most positive integer* – 1: this is #7FFFFFFFE for 32-bit machines and #7FFE for 16-bit machines. The first two instructions cause a backwards jump to be made, with a distance of up to 256 bytes; however, since most applications are larger than 256 bytes it is necessary for `ieprom` to insert a 'bounce' jump back to the start of the bootable file.
7.5.4 Bootable file

The bootable file will have been produced by the collector tool icollect, using a boot from ROM loader. The comment bootstrap, containing traceback information originally added to this file by icollect, is stripped off by ieprom.

The bootable file is placed in the EPROM such that the start of the file is placed at the lowest address, with the rest of the file being loaded in increasing address locations. The end of the file is placed immediately below the bounce jump instruction, which points to the start of the bootable file.

7.5.5 Traceback information

ieeprom creates its own traceback information consisting of the name of the control file and the time at which ieprom ran. This information is placed below the start of the bootable file. Note: at present this information is not used by any of the tools.

7.6 ieprom output files

The tool can produce output in a form readable by the user or in a form readable by EPROM programming devices. The following formats are supported:

- Binary output
- Hex dump
- Intel hex format
- Intel extended hex format
- Motorola S-record format

Whichever form is used, it is sometimes necessary to output the data in separate blocks. Block mode operation is discussed in section 7.7.

Note: there is no output for unused areas of the EPROM. If the buffer in the EPROM programmer is not initialized before loading the files produced by this program into it, unused areas of the EPROM will be filled with random data. Although the operation of the bootstrap code and loader programs will not be affected by the presence of random data, these areas of the EPROM cannot subsequently be programmed without erasing the whole device.

7.6.1 Binary output

This file is in binary format and simply contains all bytes output. There is no additional information such as address or checksums.

7.6.2 Hex dump

This simple format is intended to be used to check the output from the program. The dump consists of rows of 16 bytes each, prefixed by the address of the first
byte of each row. The format contains no characters other than the hexadecimal digits, the space character and newlines.

7.6.3 Intel hex format

This is a commonly used protocol for EPROM programming equipment. A sequence of data records is sent. Each record contains a few bytes of information, a start address and a checksum. In addition, a special record marks the end of a transmission. Since the format only supports 16-bit addresses, any longer addresses will generate an error message. Records produced by this program contain at most 32 bytes each.

7.6.4 Intel extended hex format

This format, also known as Intel 86 format, is similar to Intel hex, but adds another type of record. The new type 02 record is used to specify addresses of more than 16 bits. The type 02 record contains a 16-bit field giving a segment base offset. This value is shifted left four places and added to subsequent addresses. This mimics the operation of the segment registers on the Intel 8086 range of microprocessors. The segment base offset value persists until the next type 02 record occurs. This format therefore allows addresses up to 20 bits in length. Again, longer addresses will generate an error message. The program minimizes the number of type 02 records inserted in its output.

7.6.5 Motorola S-record format

This format is another well known industry standard; it consists of a header record, data records, and finally an image end record. The advantage of this format is that, by the use of different data record types, it can support 16, 24, or 32 bit addresses. This program uses whichever data record type is necessary.

7.7 Block mode

Block mode is a term used to describe the output from ieprom, when more than one output file is produced. The user defines how the data is to be split between files using control file statements (see table 7.4).

7.7.1 Memory organization

In order to understand the ideas behind block mode operation it is helpful to understand the way memory is organized in a 16 or 32 bit transputer.

In general, a transputer with a 32 bit data bus will expect to read from memory in 32 bit words; the addresses of these words will be on word boundaries (i.e. the address will always be divisible by 4, the two least significant bits will be 0). EPROM
devices, however, are usually 8 bits wide, and so it is necessary to have 4 EPROMs side by side to make up the 32 bit width. These 4 devices are addressed as bytes 0 to 3. The two least significant bits of an address (the 'byte selector') give the byte numbers.

Similarly a 16 bit transputer will expect to read from memory in 16 bit words. The address of each word will always be divisible by 2. The two EPROM devices required to make up the 16 bit width will be addressed as bytes 0 and 1. In this case the least significant bit of an address indicates the byte being accessed.

### 7.7.2 When to use block mode

Block mode has three uses:

- When the EPROM programmer being used is unable to split the input data into bytes, in order to program separate byte wide devices.

- When the EPROM programmer has insufficient memory to hold the entire image.

- When it is necessary, for some reason, to load the program to a different address in the EPROM programmer to that which it will occupy in the EPROM space.

### 7.7.3 How to use block mode

When block mode is to be used, the user must first decide on the blocks to be output. For each block an `output.block` statement must be specified in the control file. Each `output.block` statement must be followed by the four statements:

- `start.offset`
- `end.offset`
- `byte.select`
- `output.address`

ie prom will scan the entire image and output those bytes that have an EPROM space address between `start.offset` and `end.offset` and whose byte address matches the `byte.select` value. It will output this data to contiguous addresses starting at `output.address`.

**Note:** if the image does not occupy all of the EPROM space then there may be some space at `output.address` before the data starts.
7.8 Example control files

7.8.1 Simple output

For this example the application is in the file `bootable.btr`, there is no memory configuration, there is 128 kbytes of EPROM, and the EPROM programmer can take all of the code as one file.

```
-- EPROM description file for example 1
root.processor.type T4
bootable.file bootable.btr
eprom.space 20000
output.format srecord
output.all image.mot
```

7.8.2 Using block mode

In this example the application is in `embedded.btr`, there is a memory configuration in `fastsram.mem`, there are 16 kbytes of EPROM and the data is to be split into four blocks of 4k EPROMs to be programmed at locations 0000, 1000, 2000, and 3000 in the EPROM programmer's memory.

```
-- EPROM description file example 2
root.processor.type T8
bootable.file embedded.btr
memory.configuration fastsram.mem
eprom.space 4000
output.format intel

output.block part1.ihx
  start.offset 0000
  end.offset 3FFF
  byte.select 0
  output.address 0000

output.block part2.ihx
  start.offset 0000
  end.offset 3FFF
  byte.select 1
  output.address 1000

output.block part3.ihx
  start.offset 0000
  end.offset 3FFF
  byte.select 2
  output.address 2000

output.block part4.ihx
  start.offset 0000
  end.offset 3FFF
  byte.select 3
  output.address 3000
```
7.9 Error and warning messages

The following is a list of error and warning messages the tool can produce:

Command line parsing error

This indicates that a command line option has been specified that the tool does not recognize.

Control file error

This message will be received whenever an error is found in the format of the control file. A self explanatory message will be appended, giving details of what the tool expects the format to be.

No input file specified

This indicates that when trying to invoke the tool the user has not specified a control file to use as input.

Unable to open bootable file ‘filename’

The bootable file specified in the control file cannot be found. Check the spelling of the filename and/or that the file is present.

Unable to open configuration file ‘filename’

The memory configuration file specified in the control file cannot be found. Check the spelling of the filename and/or that the file is present.

Unable to open control file ‘filename’

The control file specified cannot be found. Check the spelling of the filename and/or that the file is present.

Unable to open output file ‘filename’

An output filename has been specified incorrectly. Check the format of the filename.
This chapter describes the librarian tool *ilibr* that integrates a group of compiled code files into a single unit that can be referenced by a program. The chapter begins by describing the command line syntax, goes on to describe some aspects of toolset libraries, and ends with some hints about how to build efficient libraries from separate modules.

### 8.1 Introduction

The librarian builds libraries from one or more separately compiled units supplied as input files. The input files may be any of the following:

- Compiled object code files produced by the INMOS compilers:
  - *oc* (occam 2 compiler),
  - *icc* (ANSI C compiler),
  - *if77* (FORTRAN–77 compiler).
- Library files already generated by *ilibr* (see section 8.2.4).
- Linked object files (see section 8.2.3).

The librarian takes a list of compiled files in TCOFF format and integrates them into a single object file that can be used by a program or program module. Each module in the input list becomes a selectively loadable module in the library. Input files can either be specified as a list on the command line or in indirect files.

The library, once built, will contain an index followed by the concatenated modules. The index is generated and sorted by the librarian to facilitate rapid access of the library content by the other tools in the toolset, for example, the linker.

Compiled object files (excluding library files) may be concatenated for convenience before using the librarian. This may prove useful when dealing with a large number of input files.

The operation of the librarian in terms of standard file extensions is shown below.
8.2 Running the librarian

To invoke the librarian use the following command line:

```
> ilibr filenames {options}
```

where: `filenames` is a list of input files separated by spaces.

`options` is a list of one or more options from Table 8.1.

Options must be preceded by '-' for UNIX-based toolsets and '/' for MS-DOS and VMS based toolsets.

Options may be entered in upper or lower case and can be given in any order.

Options must be separated by spaces.

The number of file names allowed on a command line is system dependent. To avoid overflow, files may be concatenated or an indirect file used. It is the user's responsibility to ensure that the concatenation process does not corrupt the modules, for example by omitting to specify that the concatenation is to be done in binary mode.

If no arguments are given on the command line a help page is displayed giving the command syntax.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F <code>filename</code></td>
<td>Specifies a library indirect file.</td>
</tr>
<tr>
<td>I</td>
<td>Displays progress information as the library is built.</td>
</tr>
<tr>
<td>O <code>filename</code></td>
<td>Specifies an output file. If no output file is specified the name is taken from the first input file and a <code>.lib</code> extension is added.</td>
</tr>
</tbody>
</table>

Table 8.1 ilibr command line options

Example

```
ilibr myprog.t4x myprog.t8x
```

In this example, the compiled object code files `myprog.t4x` and `myprog.t8x` (compiled for T4 and T8 transputers respectively) are used to create a library. Because no output file name is specified on the command line, the library will be given the name `myprog.lib`.

8.2.1 Default command line

A set of default command line options can be defined for the tool using the `ILIBRARG` environment variable. Options must be specified in the variable using the syntax required by the command line.
8.2.2 Library indirect files

Library indirect files are text files that contain lists of input files, directives to the librarian, and comments. Filenames and directives must appear on different lines. Comments must be preceded by the double dash character sequence ‘--’, which causes the rest of the line to be ignored. By convention indirect files are given the .lbb extension.

Indirect files may be nested within each other, to any level. This is achieved by using the #INCLUDE directive. By convention nested indirect files are also given the extension .lbb.

The following is an example of an indirect file:

```
-- user's .lbb file
userproc1.tco  -- single modules
userproc2.tco
userproc3.tco
myconcat.tco  -- concatenation of modules
#INCLUDE indirect.lbb  -- another indirect file
userproc4.tco  -- another single module
```

The contents of a nested indirect file will effectively be expanded at the position it occurred.

To specify indirect files on the command line each indirect filename must be preceded by the 'F' option.

8.2.3 Linked object input files

The librarian will also accept linked object files as input, with certain conditions. The facility to create libraries of linked modules provides an easy method of specifying input to the configurer. Such library files should only be referenced from a configuration description.

The librarian will generate an error if an attempt is made to include both linked units and compiled modules in a single library. In addition, libraries of linked object modules must not be used as input to the linker ilink. This is because the linker does not accept linked units as input files.

8.2.4 Library files as input

Library files can themselves be used as input files to ilibr. When a library file is used as a component of a new library, its index is discarded by ilibr.

Library files may not be concatenated for input to the librarian.

8.3 Library modules

Libraries are made up of one or more selectively loadable modules. A module is the smallest unit of a library that can be loaded separately. Modules are selected via the library index.
8.3.1 Selective loading

Libraries can contain the same routines compiled for different transputer types and (for occam modules) in different error modes.

Selection of library modules for linking in with the program is made on the basis of target processor type and error mode. For example, if the program is compiled for an IMS T414 only modules compiled for this processor type or for processors in a compatible transputer class are loaded. For languages such as FORTRAN and C the error mode is always UNIVERSAL.

For C and FORTRAN modules the linker selects the library modules best suited to the compilation units. For occam the compiler identifies the modules to be selected according to the requirements of the main program. The linker then makes the selection.

The linker also selects library modules for linking on the basis of usage. Only those modules that are actually used by the program are linked into the program.

8.3.2 How the librarian sorts the library index

The librarian creates a library index which is used by the linker to select the required modules. The librarian sorts the index so that for a given processor type, the optimum module is always selected by the linker.

The librarian compares and sorts modules according to a number of factors including attributes set by the compiler options used. These determine for example, the instruction set of the module and influence run-time execution times.

For example, where two library modules were derived from the same source but compiled for classes TA and T4, the librarian would place the T4 module first because it uses a larger instruction set. Modules compiled with interactive debugging enabled are placed later in the index than those for which debugging is disabled. The librarian orders the index entries such that the first valid entry is always the ‘best choice’. If two entries are found to be identical the librarian will issue a warning.

8.4 Library usage files

Library usage files describe the dependencies of a library on other libraries or separately compiled code. They consist of a list of separately compiled units or libraries referenced within a particular library. The .liu files required by the toolset’s libraries are supplied by INMOS.

If the imakef tool is used then library usage files should be created for all libraries that are supplied without source. This is to enable the imakef tool to generate the necessary commands for linking. Library usage files are text files. They may be created for a specific library by invoking the imakef tool and specifying a .liu target. See section 11.5.
Such files are given the same name as the library file to which they relate but with an .liu extension.

8.5 Building libraries

This section describes the rules that govern the construction of libraries and contains some hints for building and optimizing libraries.

8.5.1 Rules for constructing libraries

1. Routines of the same name in a library must be compiled for different transputer types, error modes or debug attributes.
2. Libraries that contain modules compiled for a transputer class (i.e. TA or TB) are treated as though they contain a copy for each member of the class (using the subset of instructions which are common).
3. Libraries that contain modules compiled in UNIVERSAL mode are treated as though they contain a copy for each of the two error modes HALT and STOP.
4. Libraries that contain modules with interactive debugging enabled are treated as though they also contain a copy with interactive debugging disabled. (When interactive debugging is enabled, channel input/output is performed via library calls otherwise transputer instructions are used).

8.5.2 General hints for building libraries

Routines that are likely to be used together in a program or procedure (such as routines for accessing the file system) can be incorporated into the same library. At a lower level, routines that will always be used together (such as those for opening and closing files) can be incorporated into the same module.

Libraries can contain the same routines compiled for different transputer types, in different error modes and with different input/output access to channels. Only those modules actually used by the program are incorporated by the compiler and linked in by the linker.

Where possible compile library input files with debugging enabled. This enables the debugger to locate the library source if an error occurs inside the library.

When building C libraries care should be taken if the 'FS' or 'FC' INMOS C compiler command line options are used, that code compatibility is maintained.

8.5.3 Optimizing libraries

It is possible for the user to optimize the size and content of any libraries which he builds himself, to target appropriate processors, improve the speed of code execution and to provide the best code for a given processor.
All libraries

Points to consider when constructing libraries in any language or mixture of languages:

- Whether the library is to be targeted at one or two specific processors or a wide range of processors. The transputer type specified for the compilation of a library module determines the instruction set used. Transputer classes TA and TB provide the basic instruction sets common to several transputer types. Transputer classes such as the T5 provide extended instruction sets but are targeted at fewer transputers than classes TA and TB.

- For floating point operations, classes T5 and TB provide better code and therefore better execution times than class TA.

- Whether the versatility of the library should be reduced in order to create a smaller library.

Libraries containing occam modules

When building libraries which include modules written in occam the same considerations apply, but also note the following:

- The error mode used will affect the size of the library. A library created from modules compiled in UNIVERSAL mode will behave as if it contains a copy of the code for both HALT and STOP mode. Also, on the current range of transputers, code compiled in HALT mode will tend to execute faster than if it is compiled in STOP or UNIVERSAL error modes.

- For libraries containing modules where the method of channel input/output may be altered, (such as in occam), both the availability of the interactive debugging facility and the speed at which the code will be executed may be affected.

When interactive debugging is enabled, channel input/output will be implemented via library calls. When interactive debugging is disabled using the compiler ‘y’ option, transputer instructions are used for channel input/output. This leads to faster execution times. However, disabling interactive debugging for one module of a program, will disable this facility for the whole program.

For a detailed description of transputer types and error modes, see appendix B.

Outlined below are three different approaches to optimization. The first approach provides the greatest level of flexibility in its application. The experienced user may refine these guidelines to specific requirements.

Semi-optimized library build targeted at all transputer types

This is the simplest way to build a library that covers the full range of transputers.
The user should compile each module separately for the following three cases and incorporate all three versions into the library.

<table>
<thead>
<tr>
<th>Processor type/class</th>
<th>Error mode</th>
<th>Method of channel I/O</th>
</tr>
</thead>
<tbody>
<tr>
<td>T2</td>
<td>UNIVERSAL</td>
<td>Via library calls</td>
</tr>
<tr>
<td>TA</td>
<td>UNIVERSAL</td>
<td>Via library calls.</td>
</tr>
<tr>
<td>T8</td>
<td>UNIVERSAL</td>
<td>Via library calls.</td>
</tr>
</tbody>
</table>

Note: Error mode and channel I/O only apply only to modules which employ them e.g. occam modules compiled by oc.

The resulting library will be small in terms of the number of modules it will contain. Due to their generic nature the modules themselves may be bulky and because they contain only the base set of instructions, the execution time for the program will tend to be slower than a more optimized approach.

Optimized library targeted at all transputer types

In order to build a library which is both generalized enough to work for all 32-bit transputers and is then optimized for modules which require extended instructions sets the following approach is recommended:

1. Compile all modules for classes TA and T8. This will provide modules which can be run on all 32-bit transputers.
2. If any of the modules perform floating point operations, compile these modules for class TB as well.

For 16-bit transputers it should be sufficient to compile all modules for class T2.

Library build targeted at specific transputer types

This method of building a library will limit the use of the library modules to specific transputer types and error modes. It is recommended as the simplest strategy to use when the following options are known for each module:

- Target transputer type.
- Error mode of modules, if any, (i.e. HALT, STOP or UNIVERSAL).
- Method of channel input/output, if any.

All modules to be included in the library must be compiled for each target transputer type and, if appropriate, for the same error mode and method of channel input/output. The resulting library may be large and contain a certain amount of duplication.

For example, for the following options:
- T414 and T425 processor types
- HALT error mode
- channel input/output via library calls

each module should be compiled for the following:

<table>
<thead>
<tr>

### 8.6 Error Messages

This section lists each error and warning message which may be generated by the librarian. Messages are in the standard toolset format which is explained in appendix A.

#### 8.6.1 Warning messages

- **filename - bad format: symbol symbol multiply exported**

  An identical symbol has occurred in the same file. There are three possibilities:

  - The same file has been specified twice.
  - The file was a library where previous warnings have been ignored.
  - A module in the file has been incorrectly generated.

- **filename1 - symbol symbol also exported by filename2**

  An identical symbol has occurred in more than one module. If the linker requires this symbol, it will never load the second module.

#### 8.6.2 Serious errors

- **bad format: reason**

  A module has been supplied to the librarian which does not conform to a recognized INMOS file format or has been corrupted.
filename - line number - bad format: excessively long line in indirect file

A line is too long. The length is implementation dependent, but on all currently supported hosts, is long enough to only be exceeded in error.

filename - line number - bad format: file name missing after directive

A directive (such as INCLUDE) has no file name as an argument.

filename - line number - bad format: non ASCII character in indirect file

The indirect file contains some non printable text. A common mistake is to specify a library or module with the F command line argument or the INCLUDE directive.

bad format: not a TCOFF file

The supplied file is not a library or module of any known type.

filename - line number - bad format: only single parameter for directive

The directive has been given too many parameters.

custom line error token

An unrecognized token was found on the command line.

filename - could not open for reading

The named file could not be found/opened for reading.

filename1 - line number - could not open filename2 for reading

The file name specified in an INCLUDE directive could not opened.

filename - could not open for writing

The named file could not be opened for writing.

filename - must not mix linked and linkable files

The librarian is capable of creating libraries from compiled modules or linked units, but it is illegal to attempt to create a library from both.

no files supplied

Options have been given to the librarian but no modules or libraries.

filename - nothing of importance in file

The file name specified in a library indirect file or in an INCLUDE directive was empty or contained nothing but white space or comments.
8.6 Error Messages

filename - line number - **only one file name per line**

More than one file name has been placed on a single line within an indirect file.

filename - line number - **unrecognised directive directive**

An unrecognized directive has been found in an indirect file.
This chapter describes the linker tool \texttt{ilink} which combines a number of compiled modules and libraries into a linked object file. The chapter begins with a short introduction to the linker, explains the command line syntax and goes on to describe linker indirect files and the main linker options. The chapter ends with a list of linker messages.

\section*{9.1 Introduction}

The linker links a number of compiled modules and library files into a single linked object file (known as a linked unit), resolving all external references. The linker may be used to link object files produced by the ANSI C compiler \texttt{icc}, the occam 2 compiler \texttt{oc}, and the FORTRAN–77 compiler \texttt{if77}. Code produced by the linker can be used as input to the configurer and collector tools to produce a bootable code file.

The linker can be driven directly from the command line or indirectly from a \emph{linker indirect file}. This is a text file which contains a list of files to be linked, together with directives to the linker.

The linker is designed to accept input files in the Transputer Common Object File Format (TCOFF) supported by this release of the toolset. However, the linker can be directed to produce output files in Linker File Format (LFF). In this format the output is compatible with either the \texttt{iboot} or \texttt{iconf} tools used by previous INMOS toolset releases.

The operation of the linker in terms of standard toolset file extensions is shown below.

\begin{center}
\begin{tikzpicture}
  \node[draw, rounded corners] (linker) {\texttt{ilink}};
  \node[draw, rounded corners, above of=linker] (lib) {\texttt{.lib}};
  \node[draw, rounded corners, left of=linker] (tco) {\texttt{.tco}};
  \node[draw, rounded corners, below of=linker] (lk) {\texttt{.lk}};
  \node[draw, rounded corners, right of=linker] (lku) {\texttt{.lku}};
  \draw[->] (linker) -- (tco);
  \draw[->] (linker) -- (lk);
  \draw[->] (linker) -- (lku);
  \draw[->] (linker) -- (lib);
\end{tikzpicture}
\end{center}

2. Pre–TCOFF toolsets, for example the Dx05 occam toolsets.

72 TDS 367 01 March 1993
9.2 Running the linker

To invoke the linker use the following command line:

```
$ ilink [filenames] {options}
```

where: `filenames` is a list of compiled files or library files.

`options` is a list of the options given in Table 9.1.

Options must be preceded by `-` for UNIX-based toolsets and `/` for MS-DOS and VMS based toolsets.
Options may be entered in upper or lower case and can be given in any order.
Options must be separated by spaces.

If no arguments are given on the command line a help page is displayed giving the command syntax.

If an error occurs during the linking operation no output files are produced.

Example of use:

**UNIX based toolsets:**

```
icc hello
ilink hello.tco -f cstartup.lnk
icconf hello.cfs
icollect hello.cfb
iserver -sb hello.btl -se
```

**MS-DOS and VMS based toolsets:**

```
icc hello
ilink hello.tco /f cstartup.lnk
icconf hello.cfs
icollect hello.cfb
iserver /sb hello.btl /se
```

In this example a compiled C file is linked for the default T414 transputer, using the standard C startup linker indirect file `cstartup.lnk`. The example also shows the steps for compiling, booting and loading the program.

</table>

Table 9.1 ilink command line options

### 9.2.1 Default command line

A set of default command line options can be defined for the tool using the ILINKARG environment variable. Options must be specified using the syntax required by the command line.

### 9.3 Linker indirect files

Linker indirect files are text files containing lists of input files and commands to the linker. Indirect files are specified on the command line using the 'F' option.
Linker indirect files can contain filenames, linker directives, and comments. File­names and directives must be on separate lines. Comment lines are introduced by the double dash ("--") character sequence and extend to the end of line. Comments must occupy a single line.

Indirect files can include other indirect files.

Linker indirect files must be created for all link operations which involve the use of imakef and either C or FORTRAN modules. For further details see section 11.4.

### 9.3.1 Linker indirect files supplied with the toolset

Linker indirect files supplied with the toolset are described in section 3.11 of the Toolset User Guide. The purpose of these files is to reference various runtime libraries (or in the case of occam, compiler libraries) required to link application programs. When specifying the program modules to be linked, the appropriate linker indirect file must be included on the linker command line.

### 9.4 Linker directives

The linker supports six directives which can be used to fine tune the linking operation. Linker directives must be incorporated in indirect files (they cannot be specified on the linker command line) and are introduced by the hash ("#") character.

The six linker directives are summarized below and described in detail in the following sections.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#alias</td>
<td>Defines a set of aliases for a symbol name.</td>
</tr>
<tr>
<td>#define</td>
<td>Assigns an integer value to a symbol name. Not applicable to occam programs.</td>
</tr>
<tr>
<td>#include</td>
<td>Specifies a linker indirect file.</td>
</tr>
<tr>
<td>#mainentry</td>
<td>Defines the program main entry point.</td>
</tr>
<tr>
<td>#reference</td>
<td>Creates a reference to a given name.</td>
</tr>
<tr>
<td>#section</td>
<td>Defines the linking priority of a module.</td>
</tr>
</tbody>
</table>

Note: Symbol names are case sensitive.

### 9.4.1 #alias basename {aliases}

The #alias directive defines a list of aliases for a given base name. Any reference to the alias is converted to the base name before the name is resolved or defined. For example, if a module contains a call to routine proc_a, which does not exist, then another routine proc_d may be given the alias proc_a in order to force the call to be made to routine proc_d.

```
#alias proc_d proc_a
```
In the above example the reference to \texttt{proc\_a} is considered to be resolved. Modules may be loaded from the library for \texttt{proc\_d} but the linker will not attempt to search for library modules for \texttt{proc\_a}. If a procedure called \texttt{proc\_a} is found in any module then an error will result as the symbol will be multiply defined.

### 9.4.2 \texttt{#define symbolname value}

The \texttt{#define} directive defines a symbol and gives it a value. This value must either be an optionally signed decimal integer, or an unsigned hexadecimal integer. (If it is the latter it must be preceded by a \texttt{#} sign). \texttt{#define} is also discussed in section 9.5.4.

Note: this directive is not applicable to occam.

### 9.4.3 \texttt{#include filename}

The \texttt{#include} directive allows a further linker indirect file to be specified. Linker indirect files can be nested to any level. The following is an example of nested indirect files:

\begin{verbatim}
-- user's .lnk file:
userprocl.tco       -- module
#mainentry proc\_a   -- main entry point directive
#include sub.lnk      -- nested indirect file
-- user's sub.lnk file:
userproc2.tco       -- further modules
userproc3.tco
userlib.lib         -- library
\end{verbatim}

### 9.4.4 \texttt{#mainentry symbolname}

The \texttt{#mainentry} directive defines the main entry point of the program i.e. the top level function of the program. This directive is equivalent to the \texttt{ME} command line option. Only one main entry point may be specified. If it is omitted the linker will select the first valid entry point in its input as a default. If there is more than one such symbol the linker will warn that there is an ambiguity.

For C and FORTRAN programs the supplied linker indirect startup files define the system main entry point.

### 9.4.5 \texttt{#reference symbolname}

The \texttt{#reference} directive creates a forward reference to a given symbol. This allows names to be made known to the linker in advance, or forces linking of library
modules that would otherwise be ignored. The purpose is to allow the inclusion of library initialization routines which might not otherwise be included. For example:

```
#reference open
```

The above example causes `open` to be included in the link, whether it is needed or not.

### 9.4.6 `#section` name

The `#section` enables the user to define the order in which particular modules occur in the executable code.

In order to use this directive the program modules must have been compiled using the compiler pragma `IMS_linkage` (C programs) or `LINKAGE` (OCCAM programs). Details of the appropriate directive can be found within the compiler reference chapter of this manual.

A compiler directive enables a section name to be associated with the code of a compilation module. A section name may take the default value "pri%text%base" or a name specified by the user.

The linker will place modules associated with the section name "pri%text%base" first in the code of the linked unit, in the order in which these modules are encountered. When the linker directive `#section` is used this default condition is overridden. The modules identified by user defined section names will be placed first in the linked module, in the order in which the `#section` directives are encountered. These will be followed by any other modules in an undefined order at the end of the linked unit.

For example:

```
#section first%section%name
#section second%section%name
```

In the above example any modules identified by `first%section%name` will be linked first, followed by modules identified by `second%section%name`, followed by any other modules.

### 9.5 Linker options

#### 9.5.1 Processor types

A number of options are provided to enable the user to specify the target processor for the linked object file, see appendix B. Only one target processor or transputer class may be specified and this must be compatible with the processor types or transputer class used to compile the modules.
If no target processor is specified, the processor type for the linked object file will default to a T414 processor type.

If any input file in the list is incompatible with the processor type in use, the link fails and an error is reported.

### 9.5.2 Error modes – options H, S and X

Linked code may be generated in three error modes. For C or FORTRAN modules, compiled respectively using `icc` or `if77`, the error mode will be UNIVERSAL. occam modules, compiled by `oc`, may be compiled in one of three error modes as shown in table 9.2.

<table>
<thead>
<tr>
<th>Error mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HALT</td>
<td>An error halts the transputer immediately.</td>
</tr>
<tr>
<td>STOP</td>
<td>An error stops the process and causes graceful degradation.</td>
</tr>
<tr>
<td>UNIVERSAL</td>
<td>Modules compiled in this mode may be run in either HALT or STOP mode depending on which mode is selected at link time.</td>
</tr>
</tbody>
</table>

Table 9.2 Error modes

Modules that are to be linked together must be compiled for compatible error modes. C and FORTRAN modules can be mixed with occam modules and occam modules compiled for different error modes may also be mixed. Table 9.3 indicates the compilation error modes which are compatible and the possible error modes they may be linked in.

<table>
<thead>
<tr>
<th>Compatible error modes</th>
<th>ilink options</th>
</tr>
</thead>
<tbody>
<tr>
<td>HALT, UNIVERSAL</td>
<td>H</td>
</tr>
<tr>
<td>STOP, UNIVERSAL</td>
<td>S</td>
</tr>
</tbody>
</table>

Table 9.3 ilink error modes

Note: Modules which have been compiled in UNIVERSAL error mode may be linked in this mode using the X option. If the resulting linked unit is then processed by the `icollect` tool it will be treated as if it had been linked in HALT mode.

The linker will produce an error if an input file is in a mode incompatible with the command line options or defaults. The linker default is to create linked modules in HALT mode unless otherwise specified.

### 9.5.3 TCOFF and LFF output files – options T, LB, LC

These three options enable the format of the linked unit output file to be changed. The linker will default to TCOFF output if none is specified.
Option T specifies that the linked unit is to be output in TCOFF format. This file may then be processed normally by other tools in the toolset, for example, the configurer and collector tools.

The LB and LC options specify that the linked unit is to be output in LFF format so that it is compatible with previous toolsets. The LB option produces a file compatible with the iboot and iconf tools used by earlier INMOS toolsets. (See footnote 2). The specified main entry point of the linked program is then available for bootstrapping by iboot or configuring by iconf. The LC option is used only in mixed language systems incorporating OCCAM programs. No main entry point need be specified.

When the LB and LC options are used the linked output file will not be compatible with the current toolset, which requires TCOFF format.

9.5.4 Extraction of library modules – option EX

The EX option instructs the linker to extract the modules which would normally have been linked by the ilink command, and to insert them unmodified into an output file. When the EX option is used, the linker does not produce a linked unit as output. Instead it outputs a concatenation of the component modules that would have made up the linked unit. This file can then itself be used as input to either the linker or librarian. By default the output file produced will have the extension .lk, although it is not a linked unit. An alternative output filename and extension can be specified using the ilink O option.

This mechanism can be used for creating sub units for linking at a later date or for extraction of modules from libraries.

When linking or extracting modules the linker attempts to resolve any unresolved references. The linker U option and the #reference directive are particularly useful for controlling the extraction of unlinked modules. For non-OCCAM modules the #define directive can also be used to refine the selection of modules which are extracted. Linker options and directives used in conjunction with the EX option do not modify the extracted modules, they just influence the selection process.

Example: Extraction from a user library

This example demonstrates how to extract sub–parts of a previously supplied library.

Suppose we are given a library, mylib.lib, which contains routines with entry-points start, run, clear, and stop. These routines may also call other modules which reside in the same library, but we are not concerned about their exact names. We can use the linker’s EX option to extract a sub–library, which just contains start, run, and stop, but does not contain clear.

We do this by forcing the linker to ‘find’ references to start, run and stop, but leave out clear.
1 Create the following linker indirect file *x.lnk*:

- Items wanted
  
  - reference start
  - reference stop
  - reference run

- Libraries
  
  mylib.lib

2 Use *ilink* to extract the required modules and place them in a named file:

```
$ ilink -f x.lnk -o sublib.tco -ex (UNIX)
$ ilink /f x.lnk /o sublib.tco /ex (MS-DOS and VMS)
```

This command will create a file called *sublib.tco* which will contain all the submodules required.

3 The librarian can then be used to create a library:

```
$ ilibr sublib.tco -o sublib.lib (UNIX)
$ ilibr sublib.tco /o sublib.lib (MS-DOS and VMS)
```

**Example: Extraction from a user library, using the run–time library**

The example demonstrates how to extract sub–parts of a previously supplied library which uses the run–time library.

Consider the same example as that described above, but where the routines *start*, *stop* and *run* have calls to the run–time library embedded inside them. We have to tell the linker not to complain about these references, because they will be resolved later, when *sublib.lib* is used.

1 We do the same as before, but we tell the linker not to complain about unresolved references, by using the *u* command line flag:

```
$ ilink -f x.lnk -o sublib.tco -ex -u (UNIX)
$ ilink /f x.lnk /o sublib.tco /ex /u (MS–DOS and VMS)
```

2 *sublib.tco* then be supplied to the librarian in the same way as before.

**Example: Extraction from a user library, for multiple processor types**

Suppose we are supplied with *mylib.lib* which contains the routines *start*, *stop*, *run*, and *clear* for both T400 and TA, and that we wish to create a library *sublib.lib* which contains everything except *clear*.

1 We use the same method as the first example to extract the T400 code:

```
$ ilink -f x.lnk -o sublib.t4 -ex -t400 (UNIX)
$ ilink /f x.lnk /o sublib.t4 /ex /t400 (MS–DOS and VMS)
```

This command will create a file called *sublib.t4* which will contain all the submodules compiled for T400.

72 TDS 367 01 March 1993
2 We do the same again for TA:

\[
\text{ilink } -f \text{x.lnk } -o \text{sublib.ta } -ex -ta \text{(UNIX)}
\]
\[
\text{ilink } /f \text{x.lnk } /o \text{sublib.ta } /ex /ta \text{(MS-DOS and VMS)}
\]

This command will create a file called \text{sublib.ta} which will contain all the submodules compiled for TA.

3 The librarian can then be used to create a library containing both:

\[
\text{ilibr sublib.t4 sublib.ta } -o \text{sublib.lib } \text{(UNIX)}
\]
\[
\text{ilibr sublib.t4 sublib.ta } /o \text{sublib.lib } \text{(MS-DOS and VMS)}
\]

Example: Generation of a completely linkable library

Suppose we have built a library \text{mylib.lib}, which requires access to the run-time library, and we wish to supply this to another person, without having to supply the run-time library separately. We can arrange for the linker to extract all the required parts of the run-time library and add them to \text{mylib.lib}.

1 Create a linker indirect file \text{x.lnk} which contains \#reference lines for each symbol in \text{mylib.lib}:

\begin{verbatim}
— Items wanted
#reference start
#reference stop
#reference run

— Libraries
mylib.lib

— Linker indirect file to access run-time library
#include occama.lnk
\end{verbatim}

The run-time library line should be adjusted depending on the type of processor which is being used:

<table>
<thead>
<tr>
<th>Language</th>
<th>When</th>
<th>Linker indirect file†</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Full run–time library</td>
<td>clibs.lnk</td>
</tr>
<tr>
<td>C</td>
<td>Reduced run–time library</td>
<td>clibsrd.lnk</td>
</tr>
<tr>
<td>occam</td>
<td>32–bit processors without an FPU</td>
<td>occama.lnk</td>
</tr>
<tr>
<td>occam</td>
<td>32–bit processors with an FPU</td>
<td>occam8.lnk</td>
</tr>
<tr>
<td>occam</td>
<td>16–bit processors</td>
<td>occam2.lnk</td>
</tr>
</tbody>
</table>

† The C linker indirect files apply to the Dx314 toolsets and the occam indirect files to the Dx305 toolsets.

2 Use \text{ilink} to extract the required modules and place them in a named file:

\[
\text{ilink } -f \text{x.lnk } -o \text{fulllib.tco } -ex \text{(UNIX)}
\]
\[
\text{ilink } /f \text{x.lnk } /o \text{fulllib.tco } /ex \text{(MS–DOS and VMS)}
\]
This command will create a file called `fulllib.teo` which will contain all the submodules required.

3 The librarian can then be used to create the extended library `fulllib.lib` which will contain the user library together with any routines which are required from the run–time library.

```bash
ilibr fulllib.teo -o fulllib.lib (UNIX)
ilibr fulllib.teo /o fulllib.lib (MS–DOS and VMS)
```

Extraction using `#define`

A module is the smallest unit the linker can extract from a library, and a module may contain several functions. It is quite likely that a module contains functions which are not required as well as functions which are referenced from modules which are required. To prevent a function from being extracted it is assigned a `dummy` value within a `#define` directive; any value will do. This causes any reference to it to be satisfied.

When the linker encounters a reference to a required function it will extract the whole module. However, if the module contains a function already specified in a `#define` directive, the function will be multiply defined and the linker will abort the extraction. It may be wise when a function is not required, to define all functions which are exported from that module, to some dummy value, thereby preventing them all from being extracted.

9.5.5 Display information – option `I`

This option enables the display of linkage information as the link operation proceeds.

9.5.6 Virtual memory – option `KB`

The `KB` option allows the user to specify how much memory the linker will use for storing the image of the users program. By default the linker will attempt to store the entire image in memory. In situations where memory is limited, an amount (~ 1 Kbytes) may be specified. If the program is larger than the amount specified then the linker will use the host filing system as an intermediate store. A reduction in speed may be expected at link time.

9.5.7 Main entry point – option `ME`

The `ME` option defines the main entry point of the program i.e. the point from which linking will start. This option is equivalent to the `#mainentry` directive and takes as its argument a symbol name which is case sensitive.

Only one main entry point may be specified. If it is omitted the linker will select the first valid entry point in its input as a default. If there is more than one such symbol the linker will warn that there is an ambiguity.
9.5.8 **Link map filename – option MO**

This option causes a link map file to be produced with the specified name. A file extension should be specified as there is no default available. By convention the first character of the extension should be 'd'; the 2nd and 3rd characters are determined by the extension of the linker object file. For example, if the linker object file takes the default extension .lku, the map file should be given the extension .dku.

If the **MO** option is not specified, a separate link map file is not produced.

A link map file is a text file containing information about the position of modules in the code file, see section 9.7. It is intended to be used as input to the *imap* tool, see chapter 12.

9.5.9 **Linked unit output file – O**

The name of the linked unit output file can be specified using the **O** option. If the option is not specified the output file is named after the first input file given on the command line and a .lku extension is added. If the first file on the command line is an indirect file the output file takes the name of the first file listed in the indirect file.

Note: Because there is no restriction on the order in which files may be listed it is up to the user to ensure that the output file is named appropriately.

9.5.10 **Permit unresolved references – option U**

The linker normally attempts to resolve all external references in the list of input files and reports any that are unresolved as errors.

Sometimes it is desirable to allow unresolved external references, for example during program development. The **U** option allows the link to proceed to completion by assuming unresolved references are to be resolved as zero. Warning messages may still be generated and the program will only execute correctly if such references are in fact redundant.

9.5.11 **Disable interactive debugging – Y**

This option applies only to the occam modules only. The option directs the linker not to use library calls for channel i/o but instead use transputer instructions, resulting in faster execution. occam modules cannot be interactively debugged if this option is used.

9.6 **Selective linking of library modules**

Library modules that are compiled for incompatible processor types or error modes are ignored by the linker. This allows library modules to be selectively loaded for specific processor types or transputer classes.
Libraries supplied with the toolset are supplied in several forms to cover the complete range of transputer types. User libraries that are likely to be used on different transputer types should be supplied for all transputer types likely to be used.

Libraries are also selected for linking on the basis of previous usage. Modules that are used by several input files are linked in only once.

### 9.7 The link map file

Module data and details of the target processor are always included in the linked unit output file in the form of a comment. This information may also be directed to a named output file by using the `mo` command line option.

The file contains a map of the code being linked and contains information which may assist the user during program debugging. It is intended as input to the `imap` tool, see chapter 12.

The map file is generated in text format and covers two categories of input file; separate compilation units, and library modules. The map consists of single line records containing a number of fields. Fields have a single character name followed by a colon. The following information is included:

#### 9.7.1 MODULE record:

A module record is created for each component module in the linked unit.

<table>
<thead>
<tr>
<th>Record name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Module number assigned by the linker.</td>
</tr>
<tr>
<td>S</td>
<td>Source filename, may be empty if string is unobtainable.</td>
</tr>
<tr>
<td>F</td>
<td>Object filename, the name of the file of library from which the module has been loaded. This will be the full path name.</td>
</tr>
<tr>
<td>O</td>
<td>File offset, the offset (in bytes) of the module within its object file.</td>
</tr>
<tr>
<td>R</td>
<td>Reference, an external symbol that is used for loading the module from a library. This field will be blank if the module was not loaded from a library.</td>
</tr>
<tr>
<td>M</td>
<td>The compilation mode, processor type/class.</td>
</tr>
</tbody>
</table>

#### 9.7.2 SECT record:

A section record is created for each section in the linked unit and shows where it is located.
9.8 Using `imakef` for version control

`imakef` tool may be used to simplify the linking of complex programs, particularly those which use libraries that are nested within other libraries or compilation units.

---

<table>
<thead>
<tr>
<th>Record name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Section number assigned by the linker.</td>
</tr>
<tr>
<td>R</td>
<td>Name of the section.</td>
</tr>
<tr>
<td>P</td>
<td>Whether the code has been placed at a fixed address; either N (no) or Y (yes).</td>
</tr>
<tr>
<td>O</td>
<td>The offset in bytes of the section within the code.</td>
</tr>
<tr>
<td>S</td>
<td>The size in bytes of the section.</td>
</tr>
</tbody>
</table>

9.7.3 MAP record:

This record shows how a region of the linked unit is mapped to a module and section.

<table>
<thead>
<tr>
<th>Record name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Module number of the module that supplied this region.</td>
</tr>
<tr>
<td>R</td>
<td>Section number of the section in which this region lies.</td>
</tr>
<tr>
<td>A</td>
<td>Address of the region, in bytes.</td>
</tr>
<tr>
<td>S</td>
<td>Size of the region, in bytes.</td>
</tr>
</tbody>
</table>

9.7.4 Value record:

This record shows the value of a symbol after linkage.

<table>
<thead>
<tr>
<th>Record name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Name of the symbol.</td>
</tr>
<tr>
<td>O</td>
<td>Name of the origin symbol – occam modules only. (Used by the linker to ensure the order of compilation is correct in respect to <code>#USE</code>).</td>
</tr>
<tr>
<td>M</td>
<td>Module number of the exporting module.</td>
</tr>
<tr>
<td>U</td>
<td>Whether the symbol has been used (externally at least); either N (no) or Y (yes).</td>
</tr>
<tr>
<td>V</td>
<td>Value of the symbol after linking. Expressed as a decimal integer or as a section number plus byte offset into that section.</td>
</tr>
</tbody>
</table>

---

72 TDS 367 01

March 1993
Note: For \texttt{imakef} to function correctly the special file extension system described in section 11.3 and appendix A \textit{must} be used.

### 9.9 Error messages

This section lists each error and warning message that can be generated by the linker. Messages are in the standard toolset format which is explained in appendix A.

#### 9.9.1 Warnings

\texttt{filename} - \texttt{bad format: reason}

The named file does not conform to a recognized INMOS file format or has been corrupted.

\textit{Size bytes too large for 16 bit target}

The code part of the linked unit has exceeded the address space of the T212 derived processor family.

\texttt{filename} - \texttt{symbol, implementation of channel arrays has changed}

Only generated in programs where \texttt{occam} code is used that was compiled in LFF format. The implementation of channel arrays in \texttt{occam} differs between the earlier \texttt{occam 2} compiler and the current TCOFF-based configurer, and channel arrays cannot therefore be used as parameters to configured procedures.

\texttt{filename} - \texttt{symbol symbol not found}

The specified symbol was not found in any of the supplied modules or libraries.

\texttt{file1} - \texttt{usage of symbol out of step with file2}

May be generated when linking programs incorporating \texttt{occam} modules with a \texttt{\#USE} directive, which causes the compiler to scan the file for details concerning certain program resources. This file \textit{must} be unchanged at link time, and the message indicates that this is not the case. There are several possible causes:

1. \texttt{file2} has been recompiled after \texttt{file1}, in which case \texttt{file1} requires recompiling.

2. The file that occurred in the \texttt{\#USE} directive has been replaced by a different version of the file at link time.

3. The file that occurred in the \texttt{\#USE} directive has not been supplied to the linker, but the linker has located a different version of a required entry point elsewhere.
The occam compiler oc may need to scan certain libraries, of which the user is unaware. Specifying one of the special occam linker indirect files occam2.lnk, occama.lnk or occam8.lnk should take care of these 'hidden' libraries.

9.9.2 Errors

filename - name clash with symbol from filename

May be generated when linking mixed language programs incorporating occam modules.

In languages such as occam entry points may be scoped, i.e. extra information is associated with each symbol to indicate which version of that entry point it is. This allows programs to be safely linked even though there are several different versions of the same entry point occurring at different lexical levels within the program.

This error indicates that a language without occam-type scoping has been mixed with a scoped language and a name conflict has occurred between a scoped and non scoped symbol.

filename - symbol symbol multiply defined

The symbol, introduced in the specified file, has been introduced previously, causing a conflict. The same module may have been supplied to the linker more than once or there may be two or more modules with the same entry point or data item defined.

filename - symbol symbol not found

The specified symbol was not found in any of the supplied modules or libraries.

filename - usage of symbol out of step with namefile

May be generated when linking programs incorporating modules with a \#USE directive which causes the compiler to scan the file for details concerning certain program resources. This file must be unchanged at link time, and the message indicates that this is not the case. There are several possible causes:

1 file2 has been recompiled after file1, in which case file1 requires recompiling.

2 The file that occurred in the \#USE directive has been replaced by a different version of the file at link time.

3 The file that occurred in the \#USE directive has not been supplied to the linker, but the linker has located a different version of a required entry point elsewhere.
The occam compiler oc may need to scan certain libraries, of which the user is unaware. Specifying one of the special occam linker indirect files occam2.lnk, occama.lnk or occam8.lnk should take care of these "hidden" libraries.

### 9.9.3 Serious errors

**filename - bad format: reason**

The named file does not conform to a recognized INMOS file format or has been corrupted.

**filename - line number - bad format: excessively long line in indirect file**

A line is too long. The length is implementation dependent, but on all currently supported hosts it is long enough so as only to be exceeded in error.

**filename - line number - bad format: file name missing after directive**

A directive (such as include) has no file name as an argument.

**filename - line number - bad format: directive invalid number**

A numeric parameter supplied to a directive does not correspond to the appropriate format.

**filename - bad format: multiple main entry points encountered**

A symbol may be defined to be the main entry point of a program by a compiler. Only one such symbol must exist within a single link.

**filename - linenumber - bad format: non ASCII character in indirect file**

The indirect file contains some non printable text. A common mistake is to specify a library or module with the 'F' command line argument or an include directive.

**filename - bad format: not linkable file or library**

The linker expects that all files names presented without a preceding switch (on the command line) or directive (in an indirect file) are either libraries or modules.

**filename - line number - bad format: only single parameter for directive**

The directive has been given too many parameters.

**Cannot create output without main entry point**

No main entry point has been specified.

**Command line: 1k minimum for paged memory option**

When using the KB option, the amount of memory used to hold the image of the program being linked is specified. There is a minimum size of 1k.
202 9.9 Error messages

Command line: *token*
An illegal token has been encountered on the command line.

Command line: bad format number
A numerical parameter of the wrong format has been found.

Command line: image limit multiply specified
The command line option 'kB' has been specified more than once.

Command line: 'load and terminate' option set, some arguments invalid
Options to load and terminate the linker have been specified in conjunction with other command line options. The linker cannot execute these options if it has been instructed to terminate first.

Command line: multiple debug modes
The command line option 'y' has been specified more than once.

Command line: multiple error modes
More than one error mode has been specified to the linker.

Command line: multiple module files specified
The command line option 'MO' has been specified more than once.

Command line: multiple output files specified
The command line option 'O' has been specified more than once.

Command line: multiple target type
More than one target processor type has been specified to the linker.

Command line: only one output format allowed
The options 'T', 'LB' and 'LC' are mutually exclusive.

*filename* - could not open for input
The named file could not be found/opened for reading.

*filename* - could not open for output
The named file could not be opened for writing.

*filename* - line number - could not open for reading
The file name specified in an include directive could not be opened.

Could not open temporary file
The 'KB' option has been used in a directory where there is no write access or not enough disc space.
The linker has been given a module to link which has been compiled with attributes incompatible with the options (or lack thereof) on the linker command line.

Invalid or missing descriptor for main entry point symbol

Applies to occam modules only. The specified main entry point to the program does not have a valid occam descriptor. This occurs if the wrong symbol name has been used, for example a data symbol in C.

Multiple main entry points specified

The main entry point has been specified on the command line or in an indirect file more than once.

The wrong number of arguments have been supplied to a directive.

The file name specified in an include directive was empty or contained nothing but white space or comments.

Various options have been given to the linker but no modules or libraries.

More than one file name has been placed on a single line within an indirect file.

The wrong number of arguments have been supplied to a directive.

When generating LFF format files, certain constructs will have no representation. For example processor types that have come into existence since the LFF format was defined.

An unrecognized directive has been found in a linker indirect file.

Tools that create modules to be linked with ilink may embed "messages" within them. Three levels of severity exist; serious, warning, and message. The docu-
mentation of the appropriate tool should be consulted for more information. The format of these messages is as follows:

- **Serious** - ilink - filename - message: message
- **Warning** - ilink - filename - message: message
- **Message** - ilink - filename - message
This chapter describes the binary lister tool ilist, which takes an object file and displays information about the object code in a readable form. The chapter provides examples of display options and ends with a list of error messages which may be generated by ilist.

10.1 Introduction

The binary lister tool ilist reads an object code file, decodes it, and displays useful information about the object code on the screen. The output may be redirected to a file. Command line options control the type of data displayed.

The ilist tool can decode and display object files produced by icc, by the linker, librarian, configurer and collector tools, and by other compatible INMOS compilers such as the occam 2 compiler oc. Files in editable ASCII format are listed without further processing.

The ilist tool will also list compilation and linked units in Linker File Format used by earlier versions of the INMOS toolsets (such toolsets are the IMS D705/D605/D505 and the D711/D611/D511 series toolsets).

Also, because ilist uses the same method to locate files as the other tools (see section A.4) it can be used to find and display the location of header files and library files in the search path specified by ISEARCH.

10.2 Data displays

There are several categories of data that can be displayed. Categories are selected by options on the command line. The main categories are:

- **Symbol data** – symbol names in each module. Information is displayed in tabular form.
- **External reference data** – names of external symbols used by each module. Information is displayed in tabular form.
- **Module data** – data for each module including target processor, compilation mode, and module file name.
- **Code listing** – code contained in each module, displayed in hexadecimal format.
- **Index data** – the content of library indexes.
- **Procedural data** – for external occam calls only.
10.2.1 Modular displays

Object code files reflect the modular structure of the original source. Single unit compilations produce a file containing a single object module, whereas units containing many compilations, such as libraries and concatenations of modules, produce object files with as many object modules. The data produced by \texttt{ilist} reflects the modular composition of object files.

10.2.2 Example displays used in this chapter

Except where indicated, the example displays used in this chapter show the output generated from the lister for the compiled (.tco) file generated by \texttt{icc} for the 'Hello World' example program. The program was compiled for a T425 processor.

10.3 Running the binary lister

To invoke the binary lister use the following command line:

\begin{verbatim}
$ ilist {filenames} {options}
\end{verbatim}

where: \textit{filenames} is a list of one or more files to be displayed.

\textit{options} is a list of one or more of the options given in Table 10.1.

\begin{tabular}{|l|}
\hline
Options must be preceded by '-' for UNIX-based toolsets and '/' for MS-DOS and VMS based toolsets.  \\
Options may be entered in upper or lower case and can be given in any order.  \\
Options must be separated by spaces.  \\
\hline
\end{tabular}

Only one filename may be given on the command line.

If no arguments are given on the command line a help page is displayed giving the command syntax.

\textbf{Note:} Options will only be applied to files of the appropriate file type. If the file cannot be displayed by the specified option, an error message is generated and the file is not displayed.

\textbf{Example of use:}

\begin{verbatim}
ilist hello.tco -a \quad \text{(UNIX based toolsets)}
ilist hello.tco /a \quad \text{(MS-DOS and VMS based toolsets)}
\end{verbatim}
### Table 10.1 ilist command line options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>A</strong></td>
<td>Displays all the available information on the symbols used within the specified modules.</td>
</tr>
<tr>
<td><strong>C</strong></td>
<td>Displays the code in the specified file as hexadecimal. This option also invokes the 'T' option by default.</td>
</tr>
<tr>
<td><strong>E</strong></td>
<td>Displays all exported names in the specified modules.</td>
</tr>
<tr>
<td><strong>H</strong></td>
<td>Displays the specified file(s) in hexadecimal format.</td>
</tr>
<tr>
<td><strong>I</strong></td>
<td>Displays full progress information as the lister runs.</td>
</tr>
<tr>
<td><strong>M</strong></td>
<td>Displays module data.</td>
</tr>
<tr>
<td><strong>N</strong></td>
<td>Displays information from the library index.</td>
</tr>
<tr>
<td><strong>O filename</strong></td>
<td>Specifies an output file. If more than one file is specified the last one specified is used.</td>
</tr>
<tr>
<td><strong>P</strong></td>
<td>Displays any procedural interfaces found in the specified modules.</td>
</tr>
<tr>
<td><strong>R reference</strong></td>
<td>Displays the library module(s) containing the specified reference. This option is used in conjunction with other option to display data for a specific symbol. If more than one library file is specified the last one specified is used.</td>
</tr>
<tr>
<td><strong>T</strong></td>
<td>Displays a full listing of a file in any file format.</td>
</tr>
<tr>
<td><strong>W</strong></td>
<td>Causes the lister to identify a file. The filename (including the search path if applicable) is displayed followed by the file type. This is the default option.</td>
</tr>
<tr>
<td><strong>X</strong></td>
<td>Displays all external references made by the specified modules.</td>
</tr>
</tbody>
</table>

**ilist** will attempt to identify the file type by its contents. If filenames only are supplied, **ilist** uses the default option 'W' and simply displays the file's identity.

Examples of **ilist** usage and the displays generated by the options can be found in succeeding sections.

### 10.3.1 Options to use for specific file types

Table 10.2 lists the available options and indicates which file formats they may be used to list. The table also lists the file types it is recommended to use with each option, in order of usefulness.
10.4 Specifying an output file – option 0

The 0 option enables the user to redirect the display data to an output file. If more than one output file is specified on the command line then the last one specified is used. File extensions should be specified, because defaults are not assumed.

Display options are described in the following sections 10.5 to 10.15. Options are given in alphabetical order.

<table>
<thead>
<tr>
<th>Option</th>
<th>Permitted file format</th>
<th>Recommended usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>Any format</td>
<td></td>
</tr>
<tr>
<td>O</td>
<td>Any format</td>
<td></td>
</tr>
<tr>
<td>T</td>
<td>Any format</td>
<td></td>
</tr>
<tr>
<td>W</td>
<td>Any format</td>
<td></td>
</tr>
<tr>
<td>A</td>
<td>TCOFF only</td>
<td>.lib, .tco, .lku</td>
</tr>
<tr>
<td>C</td>
<td>TCOFF only</td>
<td>.tco, .lku, .lib</td>
</tr>
<tr>
<td>E</td>
<td>TCOFF only</td>
<td>.lib, .tco, .lku</td>
</tr>
<tr>
<td>M</td>
<td>TCOFF only</td>
<td>.tco, .lku, .lib</td>
</tr>
<tr>
<td>N</td>
<td>TCOFF libraries only</td>
<td>.lib</td>
</tr>
<tr>
<td>P</td>
<td>TCOFF only</td>
<td>.lib, .tco, .lku</td>
</tr>
<tr>
<td>R</td>
<td>TCOFF libraries only</td>
<td>.lib</td>
</tr>
<tr>
<td>X</td>
<td>TCOFF only</td>
<td>.lib, .tco, .lku</td>
</tr>
</tbody>
</table>

Table 10.2 Recommended options

10.3.2 Output device

`ilist` sends its output to the host standard output stream, normally the terminal screen. Facilities available on the host system may allow you to redirect the output to a file, or send it to another process, such as a sort program. For details of these facilities consult the documentation for your system. Alternatively the `ilist 'O'` command line option may be used to redirect output to a specified file.

10.3.3 Default command line

A set of default command line options can be defined for the tool using the ILIS-TARG environment variable. Options must be specified using the syntax required by the command line.
10.5 Symbol data – option A

This option displays all the available information about the symbols used within the specified modules. A tabular format is used.

Note: The data produced by this display is extensive and detailed and assume some knowledge of the object file format.

The following information is given:

- Symbol name.
- Section attributes, if applicable.
- Symbol attributes.
- The number of the symbol within the module plus the number of its origin.
- Module name.
- Target processor.
- Error mode.
- Interactive debugging – if disabled indicated by the presence of a ‘y’ character. If this field is blank then interactive debugging is enabled.

10.5.1 Specific section attributes

Certain attributes apply only to symbols which are section names. If they are applicable, these attributes are indicated by the following nomenclature and displayed as a character string:

<table>
<thead>
<tr>
<th>R</th>
<th>Read section.</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>Write section.</td>
</tr>
<tr>
<td>X</td>
<td>Execute section.</td>
</tr>
<tr>
<td>D</td>
<td>Debug section.</td>
</tr>
<tr>
<td>V</td>
<td>Virtual section.</td>
</tr>
</tbody>
</table>

10.5.2 General symbol attributes

Attributes for all symbols, including section names, are also indicated by a character string, using the following nomenclature:
Symbol attributes are displayed immediately after the section attributes, and each attribute is displayed at a specific position in the string. Attributes which are not present are indicated by a hyphen '-'.

The position of each attribute in the string is as follows:

RWXDV LEIWCupo

10.5.3 Example symbol data display

Figure 10.1 shows the symbol data display for the compiled file hello.tco.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>Symbol local to the module.</td>
</tr>
<tr>
<td>E</td>
<td>Symbol exported from the module.</td>
</tr>
<tr>
<td>I</td>
<td>Symbol imported to the module.</td>
</tr>
<tr>
<td>W</td>
<td>Weak attribute, indicates that the symbol takes the value 0 when not defined.</td>
</tr>
<tr>
<td>C</td>
<td>Conditional attribute, indicates that the first value given to the symbol is always used.</td>
</tr>
<tr>
<td>U</td>
<td>Unindexed, indicates that the symbol is not present in the library index.</td>
</tr>
<tr>
<td>P</td>
<td>Provisional attribute, indicates that the last value given to the symbol is always used.</td>
</tr>
<tr>
<td>O</td>
<td>Indicates that the symbol is an origin symbol. The origin symbol is used by the linker to check the origin of the module.</td>
</tr>
</tbody>
</table>

Figure 10.1  Example output produced by the A option.

10.6 Code listing – option C

The 'C' option produces a full listing of the code in the same format as that generated by the 'T' option, but with the addition of a hex listing of the code at each LOAD_TEXT directive. This option may be accompanied by the 'T' option; if the 'T' option is not specified it is supplied automatically.
The output from this option gives an ASCII dump, in hexadecimal format, of the code for each module. It can be used on any object code.

When used to display object code produced by the occam compiler, the code for each module is displayed as a contiguous block of lines, where each line has the format:

```
address   ASCIIhex   ASCII characters
```

where: `address` is the address of the first byte on the line, expressed as an offset from the start of the module.

`ASCII hex` is the hex representation of the code

`ASCII characters` are the ASCII characters corresponding to the hex code.

In all cases code is read from left to right. If a value is not printable it is replaced by a dot `.DOT. .`

### 10.6.1 Example code listing display

Figure 10.2 shows the code listing display for the compiled file `hello.teo`.

Figure 10.2 Example output produced by the C option

72 TDS 367 01 March 1993
10.7 Exported names – option E

The output from this option is in a tabular format. It consists of a list of names exported by the modules. This option also displays any globally visible data. The following information is given by the display:

- Exported name.
- The name of the module in which the exported name is found.
- Language used.
- Target processor.
- Error mode.
- Interactive debugging – if disabled indicated by the presence of a 'Y' character. If this field is blank then interactive debugging is enabled.

10.7.1 Example exported names display

Figure 10.3 shows the exported names display for the compiled file hello.tco.

```
main   -> hello.c   ANSI_C   T425 X
```

Figure 10.3 Example output produced by the E option

10.8 Hexadecimal/ASCII dump – option H

This option provides a display of the specified files in hexadecimal and ASCII format. The option does not attempt to identify file types and may be used to display any files which the lister has previously identified incorrectly.

The output takes the form of a hexadecimal representation of the whole of the file content. The display has a similar appearance to that produced by the C option, however, the C option only functions on code found within the file.

Each module is displayed as a contiguous block of lines, where each line has the format:

```
address  ASCII hex  ASCII characters
```

where: address is the address of the first byte on the line, expressed as an offset from the start of the module.
ASCII hex is the hex representation of the code

ASCII characters are the ASCII characters corresponding to the hex code.

In all cases code is read from left to right. If a value is not printable it is replaced by a dot ‘.’.

10.8.1 Example hex dump display

Figure 10.4 shows the hex dump display for the compiled file hello.teo.

Figure 10.4 Example output produced by the H option

10.9 Module data – option M

This option displays any header information which is present. This may include version control data, general comments that may have been appended to the file during use of the toolset and copyright information. The data is displayed for individual modules in the object file and includes:

- Module name
- Transputer type and compilation error mode
- Language type
- Version control data
- Comments inserted by the toolset, for example, copyright clauses.

Data is displayed in separate blocks for each module. Some of the data is also used by other tools in the toolset, for example, some comments are used by the
debugger tool `idebug` while version information is used by some tools for compatibility testing.

When linked units are displayed using this option, a long comment will be displayed. This comment gives details of the allocation of memory to each separately compiled code and library module used in the linked module. The following information is given in tabular format:

- Code type - Separately compiled code (SC) or library module (LIB).
- Module name.
- Address offset in linked module.
- Start address.
- End address.
- Reference in library (if applicable) used to locate the relevant library module.

10.9.1 Example module data display

Figure 10.5 shows the module data display for the compiled file `hello.teo`.

```
MODULE: ANSI_C T425 X
VERSION: icc hello.c
```

Figure 10.5 Example output produced by the M option

10.10 Library index data – option N

This option is used to list library indexes. The data is given in a tabular format. For each entry in the index the following information is given:

- The address of the module in the library.
- The symbol name.
- The language the module is written in.
- The target processor type.
- The error mode used.
- Interactive debugging – if disabled indicated by the presence of a ‘Y’ character. If this field is blank then interactive debugging is enabled.
10.10.1 Example library index display

Figure 10.6 shows part of the output produced by the ‘N’ option for one of the standard C library files.

```
00025C21 ie64op.pax:8340AC71 OCCAM TA X
00036155 xlinkl.pax:F11BAD5A OCCAM TA X
00034AF7 DATAN2%c OCCAM TA X
000330D0 DCOS%c OCCAM TA X
0000B898 DefaultSignalHandler%c ANSI_C TA X
0001C666 floorf ANSI_C TA X
0002007B get_static_size%c ANSI_C TA X
000129AD sub_vfprintf%c ANSI_C TA X
```

Figure 10.6  Example output produced by the N option

10.11 Procedural interface data - option P

This option is only applicable to occam modules or mixed language programs. It displays procedural interface information for all external occam functions and procedures. The following information is displayed for each module:

- Target processor.
- Error mode.
- Language used.
- Amount of workspace used by the procedure or function, in words.
- Amount of vector space used by the procedure or function, in words.
- Parameters used by the procedure or function.
- Data type of parameters.
- Channel usage, if applicable.

Channel usage is displayed in occam notation. A channel marked with an ? is an input channel to the code of that entry point, and a channel marked with ! is an output channel.

When a library file is listed this will be indicated by the words ‘INDEX ENTRY mode’ rather than ‘DESCRIPTOR mode’.

10.11.1 Example procedural data display

Figure 10.7 shows an example procedural data display for a compiled occam module. This example is taken from the 'simple' example occam program compiled by oc for the TA processor class.
10.12 Specify reference – option $R$

This option is used in conjunction with any of the other display options to locate a specific symbol within a named library. All library modules that export the symbol are displayed.

The exact format of the display depends on the main display option with which $R$ is used.

**Note:** Symbol names must be specified in the correct case.

10.13 Full listing – option $T$

This option displays all data found in the input file. Provided that $ilist$ recognizes the file type, the file is decoded in its own format. Text file are displayed as text and unrecognized file types are displayed as a hexadecimal dump.

Data is not displayed in a tabular form but is output in the sequence in which it is found in the module.

The display formats are tailored to each file format and are intended for diagnostic support and analysis; large amounts of data are produced which may require skilled interpretation.

10.13.1 Example full data display

Figure 10.8 shows the full data display for the compiled file $hello.tco$. 

---

```
PROC simple(CHAN OF SP fs,CHAN OF SP ts)
SEQ
  fs?
  ts!
;  
```

Figure 10.7  Example output produced by the $P$ option
10.13.2 Configuration data files

The full data listing of a configured (.cfb) file shows how the processes are mapped onto a transputer system and has a different appearance to other displays produced by this option.

10.14 File identification – option w

This option causes the lister to identify the file type. ilist takes a heuristic approach to file identification. The filename is displayed along with the file type. The full path to the file is also displayed if the file is not in the current directory (i.e. if it has been found in the search path specified in the ISEARCH environment variable). This is the default command line invocation if no other option is supplied.

Table 10.3 indicates how the lister classifies file types.
Table 10.3  File types recognised by ilist

where: SC files are separately compiled files.

LFF files are separately compiled or linked files in LFF format.

Extracted files are files which have been compiled and developed to be dynamically loaded onto a transputer system.

iboot programs are programs which have had a bootstrap added by the iboot tool, supported by previous issues of the toolset i.e. the IMS D711/D611/D511 and D705/D605/D505 series toolsets.

10.14.1 Example file identification display

Figure 10.9 shows the file identification display for the compiled file hello.tco. and two linker control files. This output was generated by the following command:

    ilist hello.tco occama.lnk clibsrd.lnk
10.15 External reference data – option x

This option displays a list of all the code and data symbols imported by the modules specified to the lister, i.e. it lists their external references. External references are references to separately compiled units. For C programs the option will also display any external references to globally visible data.

The output from this option is in a tabular format. It consists of a list of external references and their associated modules. The following information is displayed:

- External reference i.e. name of the separately compiled unit.
- The name of the module in which the external reference exists.
- Language used.
- Target processor.
- Error mode.
- Interactive debugging – if disabled indicated by the presence of a ‘Y’ character. If this field is blank then interactive debugging is enabled.

10.15.1 Example external reference data display

Figure 10.10 shows the external reference data display for the compiled file hello.tco.

```
.IMS_printf <- hello.c ANSI_C T425 X
```

Figure 10.10  Example output produced by the X option

10.16 Error messages

This section lists error and warning messages that can be generated by the lister. Messages are in the standard toolset format which is explained in appendix A.

72 TDS 367 01
March 1993
10.16 Error messages

10.16.1 Warning messages

*filename* - *reason*

The named file does not conform to a recognized INMOS file format or has been corrupted.

10.16.2 Serious errors

*filename* - *bad format*: *reason*

The named file does not conform to a recognized INMOS file format or has been corrupted.

*filename* - *could not open for input*

The named file could not be found/opened for reading.

*filename* - *could not open for output*

The named file could not be opened for writing.

*filename* - *file type does not correspond to command line options*

The options given to the lister apply to formats dissimilar to the format of the file being read.

**must supply additional** TCOFF **options with reference** *reference*

The required format of the listing has not been specified.

*filename* - *no entry for reference in library index*

The specified reference cannot be found in the library index.

parsing command line *token*

An unrecognized token was found on the command line.

*filename* - *unexpected end of file*

The named file does not conform to a known INMOS file format or has been corrupted.
This chapter describes the makefile generator imakef that creates makefiles for input to make programs. It explains how the tool can be used to create makefiles and describes the special file naming conventions that allow imakef to create makefiles for mixtures of code types. The chapter describes the format of makefiles generated by imakef and ends with a list of error messages.

11.1 Introduction

Make programs automate program building by recompiling only those components that have been changed since the last compilation. To do this they read a makefile which contains information about the interdependencies of files with one another, along with command lines for rebuilding the program.

imakef creates makefiles for all types of toolset object files, using its built-in knowledge of how files referenced within the target file depend on one another. It is intended to be used with all INMOS compiler systems that generate TCOFF object code, which includes the the ANSI C compiler icc, the occam 2 compiler oc and the FORTRAN-77 compiler if77. Its mode of operation with different languages is controlled by command line options. The makefile is generated in a standard format for input to most make programs.

Makefiles created using imakef are compatible with many public domain and proprietary make programs. The following make programs are directly compatible:

- Borland make.
- UNIX make.
- Microsoft nmake.
- Gnu make.

However, the older Microsoft make program "make" is not compatible.

The source of imakef is supplied with the toolset so that it can be modified for use with other make programs.

11.2 How imakef works

imakef operates by working back from the target file to determine its dependencies on other files, using its knowledge of inputs and outputs of each tool and
the compilation architecture of the toolset. For example, compiled object files must be created from language source files using the compiler.

In a similar way linked files must be generated from compiled files. `imakef` assumes that programs targeted at a single transputer are not required to be configured. Bootable files may therefore be generated from linked units or configuration data files. `imakef` works back from the target file, determining file dependencies and creating commands to recreate the target file, recompiling and relinking where necessary.

### 11.3 File extensions for use with `imakef`

`imakef` identifies files and file types by a special set of file extensions which identify the transputer target type and compilation error mode. This allows the tool to produce makefiles for mixed module combinations.

**Note:** The extensions that `imakef` requires differ in most cases from the standard toolset default extensions which are described in section A.5. For `imakef` to work correctly the extensions described in section 11.3.1 must be used on all intermediate and target files, at all stages of program development i.e. compiling, linking, configuring, and booting.

The file naming convention uses a three-character extension which identifies the type of file and in most cases includes the transputer target and error mode. Source files for the most part use standard language extensions.

#### 11.3.1 Target files

The following table lists the types of object code files for which `imakef` can create makefiles, along with the file extension formats that must be used.

<table>
<thead>
<tr>
<th>Target file</th>
<th>File extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compiled code.</td>
<td>.txx</td>
</tr>
<tr>
<td>Linked code.</td>
<td>.cxx</td>
</tr>
<tr>
<td>Bootable code for single transputer programs.</td>
<td>.bxx</td>
</tr>
<tr>
<td>Bootable code for multitransputer programs.</td>
<td>.btl</td>
</tr>
<tr>
<td>Dynamically loadable code.</td>
<td>.rxx</td>
</tr>
<tr>
<td>Libraries.</td>
<td>.lib</td>
</tr>
<tr>
<td>Configuration binary file.</td>
<td>.cfb</td>
</tr>
<tr>
<td>Library usage file.</td>
<td>.liu</td>
</tr>
<tr>
<td>Library indirect file.</td>
<td>.lbb</td>
</tr>
</tbody>
</table>

Compiled, linked, bootable and non-bootable files, whatever their language origin, have a transputer target designator as the second character of the extension, and
an error mode designator as the *third* character. Accepted values of these designators are listed below.

<table>
<thead>
<tr>
<th>2nd Character</th>
<th>Transputer types supported</th>
<th>3rd Character</th>
<th>Error mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>T212, T222, M212</td>
<td>x</td>
<td>UNIVERSAL</td>
</tr>
<tr>
<td>3</td>
<td>T225</td>
<td>h</td>
<td>HALT</td>
</tr>
<tr>
<td>4</td>
<td>T414</td>
<td>s</td>
<td>STOP</td>
</tr>
<tr>
<td>5</td>
<td>T426, T425, T400</td>
<td></td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>T800</td>
<td></td>
<td></td>
</tr>
<tr>
<td>9</td>

<td></td>
<td></td>
</tr>
<tr>
<td>a</td>
<td>Class TA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>b</td>
<td>Class TB</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Examples:

- `.t4x` - refers to a compiled module targeted for T4 transputers, in UNIVERSAL error mode.
- `.tah` - refers to a module targeted for any 32-bit transputer in HALT error mode.

Compiled code generated by `icc` or `if77` is in UNIVERSAL mode, designated by the character ‘x’. HALT and STOP code can be generated by the occam 2 compiler `oc`.

Transputer types are explained further in section B.2.

Program development using `imakef` and the extensions to use are illustrated in Figure 11.1. Target files which can be created by `imakef` are shown in bold.
Figure 11.1 Main target files showing extensions required
11.4 Linker indirect files

For C and FORTRAN modules linker indirect files must be created for all linked units where imakef will be used to generate a target file. Linker indirect files define to imakef the components of the linked unit, providing a starting point for working out file dependencies.

Linker indirect files must be named after the linked unit to which they relate and carry the .lnk extension.

For programs written wholly in occam, imakef will automatically generate a linker indirect file. The file is named after the target filename but is given an extension in the form .lxx. The file contains a list of modules to be linked. In addition an #INCLUDE statement references a further linker indirect file, referencing compiler libraries. imakef deduces the compiler libraries to be included from the extension of the linked object file.

Section 11.6.2 provides a short description of linker indirect files and several examples are given in section 11.7.

11.5 Library indirect and library usage files

When building a library using imakef, a file must be provided that contains the names of all the object modules required to build the library. This file is known as a library indirect file and has the extension .lbb. See chapter 8 for further details.

Library usage files describe the dependencies of a library on other libraries or separately compiled code. They contain a list of files to which the library must be linked before it can be run, and ensure that the correct linker commands are generated.

Library usage files should be created for all user-defined libraries where the source of the library is not available. They are created using imakef.

Library usage files are given the same name as the library to which they relate, but with a .liu extension. To create a library usage file using imakef, specify the library name and add a .liu extension. For example, the following command creates a library usage file for the library mylib.lib:

imakef mylib.liu

When imakef is used to create a library usage file no makefile is generated.

11.6 Running the makefile generator

The imakef tool takes as input a list of files generated by tools in the toolset and generates a makefile, containing full instructions of how to build the application.
11.6 Running the makefile generator

program. The output file is named after the first target filename and is given a .mak extension (if no output file is specified on the command line).

To invoke imakef use the following command line:

\[ \textit{imakef} \textit{filenames} \{ \textit{options} \} \]

where: \textit{filenames} is a list of target files for which makefiles are to be generated. If more than one file is specified the single makefile generated will generate all of the specified files.

\textit{options} is a list, in any order, of one or more options from Table 11.1.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>This option is used when incorporating C or FORTRAN modules into the program. It specifies that the list of files to be linked is to be read from a linker indirect file. This option must be specified for correct C or FORTRAN operation.</td>
</tr>
<tr>
<td>D</td>
<td>Disables the generation of debugging information in compilations. The default is to compile with full debugging information.</td>
</tr>
<tr>
<td>I</td>
<td>Displays full progress information as the tool runs.</td>
</tr>
<tr>
<td>M</td>
<td>Produce compiler, linker and collector map files for imap.</td>
</tr>
<tr>
<td>NI</td>
<td>Files in the directories in ISEARCH are not put into the makefile. This means that system files are not present, making it much easier to read.</td>
</tr>
<tr>
<td>O \textit{filename}</td>
<td>Specifies an output file. If no file is specified the output file is named after the target file and given the .mak extension.</td>
</tr>
<tr>
<td>R</td>
<td>Writes a deletion rule into the makefile.</td>
</tr>
<tr>
<td>Y</td>
<td>Disables interactive (breakpoint) debugging in all compilations. The default is to compile with full breakpoint debugging information.</td>
</tr>
</tbody>
</table>

Table 11.1 imakef options
11.6.1 Example of use

```
imakef hello.b4x -c  (UNIX based toolsets)
imakef hello.b4x   /c (MS-DOS and VMS based toolsets)
```

This creates the makefile `hello.mak` which when used as input to make generates the bootable file `hello.b4x` (a bootable file for T4 transputers).

11.6.2 Specifying language mode

`imakef` can be used with all compilers in the INMOS TCOFF family. This includes the ANSI C compiler `icc`, the occam compiler `oc` as well as the FORTRAN compiler `if77`.

`imakef` has two modes of operation: one for the traditional languages FORTRAN and C, and another for occam. occam mode is the default; FORTRAN and C operation is controlled by a command line option.

In occam programs, file dependencies are wholly deducible from the source and target files. In FORTRAN and C programs the list of files to be processed by the linker must be created in a linker indirect file; use of the `imakef 'C'` option instructs `imakef` that there are linker indirect file(s) to be read. The linker indirect files must include all the components of a program, including any libraries that are used.

The 'C' option must be specified for all C and FORTRAN programs and for any mixed language programs which incorporate modules in these languages. For mixed language programs all files which are to be linked must be listed in the linker indirect file(s), including any occam modules or library files. In systems that use mixtures of code compiled for different transputer types and error modes, a separate linker indirect file must be created for each.

An example is given in section 11.7.3 of how `imakef` may be used to build a mixed language program.

11.6.3 Configuration description files

When `imakef` builds a makefile for a configured program it will look for the presence of a configuration description file which has the same name as the program to be built.

The type of file searched for depends on the mode of operation specified to `imakef`. If the default occam mode is used, that is, the 'C' option is not specified, `imakef` will look first for a configuration description file with the extension `.pgm`, (readable by the occam configurer `occonf`). If a `.pgm` file is not present `imakef` will then look for a `.cfs` file (readable by the 'C-style' configurer `icconf`).

If the FORTRAN/C mode is used, that is, the 'C' option is specified, the reverse sequence is used, that is, `imakef` looks first for a `.cfs` file.
11.6.4 Disabling debug data

Two options to `imakef` disable the creation of debug data.

The 'D' option disables the generation of all debugging information in the target file. If this option is used the resulting target code cannot be debugged.

The 'Y' option disables only the data required for interactive (breakpoint controlled) debugging. If this option is given no breakpoint debugging operations can be used on the final program. Post-mortem debugging is unaffected.

11.6.5 Removing intermediate files

Intermediate files can be removed by specifying the 'R' option to `imakef`. This adds a delete rule to the makefile which directs make to remove all intermediate after the program is built. The delete operation is only honored if make is subsequently invoked with the DELETE option.

11.6.6 Files found on ISEARCH

When `imakef` runs, it includes all dependencies in the set of rules. The NI option prevents `imakef` recording in the makefile, any dependencies on files found using ISEARCH. As a result the makefile is easier to read and is more portable.

11.6.7 Map file output for `imap`

Using the 'M' option, `imakef` can be made to generate switches in the calls to the compiler, linker or collector to output map files. These map files are then available for reading by the `imap` tool, details of which can be found in chapter 12.

11.7 `imakef` examples

This section contains several examples of the use of `imakef` with different programming languages. The final example shows how a mixed language program can be built with `imakef`.

The sources appropriate to the toolset are supplied in the examples subdirectory.
11.7.1 C examples

The first example shows how to create a makefile for a multi-module program, written in C, running on a single transputer. The second example shows how to create a makefile for a configured C program.

Single transputer program

This first example is for a program which is not configured.

The example program is made up of three source files, written in C:

- main.c
- hellof.c
- worldf.c

`imakef` needs to know the names of the main components of the program, and looks for the associated linker indirect file `hello.lnk`:

`hello.lnk` must contain the following text:

```
main.t4x
hellof.t4x
worldf.t4x
#include cnonconf.lnk
```

Note: the use of the `.t4x` extension rather than `.tco`. This is because `imakef` needs to work out the required processor type. The startup linker indirect file `cnonconf.lnk` is also included. The inclusion of this file is standard for all C programs which are not configured and directs `imakef` to include the libraries. To create the makefile use the command:

```
imakef hello.b4x -c (UNIX based toolsets)
imakef hello.b4x /c (MS-DOS and VMS based toolsets)
```

Note: the use of the `.b4x` extension instead of `.bt1`. Using this form of extension informs `imakef` that we wish to create a bootable program for a single transputer without the aid of the configurer. The makefile `hello.mak` is created.
Multitransputer program

This example program uses the configurer to place linked units on two processors. The program is made up of the following source files written in C:

master.c
mult.c
multi.cfs

The .cfs file is the configuration description file. It places 2 linked units on 2 processors, using the following statements:

use "master.c8x" for master;
use "mult.c4x" for mult;

Note: the use of the .cxx form of extension instead of the toolset default extension for linked units .lku. imakef reads the .cfs file and determines that the program is made up of two linked units, each of which must have an associated linker indirect file, namely, master.lnk, and mult.lnk.

The two linker indirect files files must contain the following text:

master.lnk:

master.t8x
#include cstartup.lnk

mult.lnk:

mult.t4x
#include cstartrd.lnk

Again note the use of the .txx form of extension. master.lnk includes the linker indirect file cstartup.lnk, which is used for configured programs linked with the full runtime library. mult.lnk includes cstartrd.lnk, the standard linker indirect file used for configured programs linked with the reduced library. This library can be used by mult.t4x because the module does not require host access.

To create the makefile use the following command:

imakef multi.btl -c (UNIX based toolsets)
imakef multi.btl /c (MS-DOS and VMS based toolsets)

The .btl extension informs imakef that the target is a configured program, to be built from a configuration description file called multi.cfs. The makefile multi.mak is created.

Note: when multi.mak invokes the configurer, the following warning is issued:

Warning–icconf–Using single hop software virtual links

This warning may be ignored.
11.7.2 occam examples

Two examples are again provided, the first for a multi-module program running on a single transputer and the second example for a configured program.

Single transputer program

The example program is made up of four source files, written in occam:

- sorthdr.inc
- element.occ
- inout.occ
- sorter.occ

The sources are the same as those used in the sorter example described in the Toolset User Guide.

To create the makefile use the following command:

```
imakef sorter.b4h
```

Note the use of the .b4h extension instead of .btl. Using this form of extension informs imakef that we wish to create a bootable program for a single transputer without the aid of the configurer.

The makefile generator has built-in knowledge of the file name rules for occam. In this example, it knows by examining the file name that the program to be built is for a single T414 processor in HALT mode, and that the source of the main body of the program is in the file sorter.occ. It reads the file sorter.occ and discovers that it uses a library called hostio.lib, the two compilation units inout and element, and two include files, sorthdr.inc and hostio.inc. It then reads the sources of the include files and compilation units and finds no more file dependencies.

With this information about source file and their dependencies, imakef builds a makefile called sorter.mak containing full instructions on how to build the program and creates a linker indirect file sorter.14h (see section 11.4).

To build the program run the make program on sorter.mak. The entire program will be automatically compiled, linked and made bootable, ready for loading onto the transputer.
Multitransputer program

This version of the sorter program is configured to place linked units on four processors. It is based on the configured sorter program described in the Toolset User Guide and uses the same sources.

The program is made up of the following occam files:

- sorthdr.inc
- element.occ
- inout.occ
- sortconf.pgm

To create the makefile use the following command:

imakef sortconf.btl

The .btl extension informs imakef that the target is a configured program, to be built from a configuration description file called sortconf.pgm. The configuration description references two linked units:

#USE "inout.c4h"
#USE "element.c4h"

Note: the use of the .cxx form of extension instead of the toolset default extension for linked units .lku. imakef reads the .pgm file and will produce a file called sortconf.mak containing a make description of the program.

To build the program run the make program on sortconf.mak.
11.7.3 Mixed language program

This example uses a mixed language program which combines both occam and C modules. It is based on the example given in the 'Mixed language programming' chapter of the accompanying User Guide.

The example program is made up of the following files:

- `mixed.t4h` - Compiled occam module
- `cfunc.t4x` - Compiled C module

where: the occam module is the main program which calls in the C function.

To create the makefile for the example program use one of the following commands:

```
imakef mixed.b4h -c  
imakef mixed.b4h /c
```

This command informs `imakef` that we wish to create a bootable program for a single T414 processor in HALT mode. The 'c' option tells `imakef` that the program also includes modules written in C.

`imakef` needs to know the names of the C components of the program, and looks for the associated linker indirect file `mixed.lnk`. Because a linker indirect file is supplied to `imakef`, all the modules to be linked must be listed.

`mixed.lnk` must contain the following files:

```
mixed.t4h  
cfunc.t4x  
callc.lib  
hostio.lib  
#include clibsrd.lnk  
#include occama.lnk
```

The occam module is listed first, because it contains the main entry point of the program. Note: the use of the `.t4h` and `.t4x` extensions. The C module has been compiled in UNIVERSAL mode, which is the standard mode for the C compiler. This does not cause a problem because UNIVERSAL mode may be called by HALT mode.

The files `hostio.lib` and `callc.lib` are the occam libraries. `occama.lnk` contains a list of occam compiler libraries which may be required.

`clibsrd.lnk` references the reduced C runtime library used by the C module.

With this information `imakef` builds the make program `mixed.mak`.

72 TDS 367 01 March 1993
Further information about mixed language programming can be found the accompanying User Guide.

11.8 Format of makefiles

Makefiles essentially consist of a number of rules for building all the parts of a program. Each rule contains two main elements: a definition of the file's dependencies in a format acceptable to make programs; and the command to recreate the file on a specific host. All makefiles also contain macros which define command strings and option combinations.

11.8.1 Macros

All makefiles created by `imakef` include a set of macro definitions inserted at the head of the file.

Macros define strings which are used to call the compiler, the configurer, the linker, the librarian, the collector, and the eprom formatter tools, and fixed combinations of options for these tools.

Macros are provided so that customized versions of the toolset commands, and specific combinations of options, can be easily incorporated. Existing macros can be modified for specific host environments, and new macros created, by editing the makefile.

The full set of macros defined by `imakef` can be found by consulting any makefile created by the tool.

11.8.2 Rules

Rules define the dependencies of object files on other files and specify action strings to build those files.

Example:

UNIX based toolsets:

```
example.t4h : example.c
  $(CC) example -t4 -h -o example.t4h $(COPT)
```

MS-DOS and VMS based toolsets:

```
example.t4h : example.c
  $(CC) example /t4 /h /o example.t4h $(COPT)
```

This rule first defines the target as the compiled program `example.t4h`, which is dependent on the source file `example.c` and then specifies the command that must be invoked to build it.
The first rule in all makefiles is for the main target. Succeeding rules define subcomponents of the main target, and are listed hierarchically.

**Action strings**

Action strings define the complete command line needed to recreate a specific file. The format is similar for all tools and consists of a call to the tool via a predefined macro, a fixed set of parameters, a list of command line options, probably also via a macro, and the output filename. (The output file is specified on the command line so that the rebuilt file is always written to the directory that contains the source.)

**11.8.3 Delete rule**

The delete rule directs make to remove all intermediate object files once the program has been built. It consists of a single labelled action string which invokes the host system 'delete file' command. Deletion is only performed if make is subsequently invoked with the DELETE option.

The delete rule is appended to the makefile by specifying the `imakef 'R'` option.

**11.8.4 Editing the makefile**

Makefiles created by the `imakef` tool can be edited for specific requirements. For example, new macros can be added and new rules defined for compiling and linking code written in other languages.

**Adding options**

`imakef` generates action strings which have the minimum of options for each tool. In most cases additional options are unnecessary or may be specified using compiler directives. To modify the set of default options for a particular tool simply edit the appropriate macro in the makefile.

For example, if the output of progress information is to be enabled for all invocations of the compiler, the compiler ‘I’ option would be added to the macro which defines the standard combination of options for invoking the compiler. Alternatively a new macro containing only the ‘I’ option could be defined and added to each compiler action string.

**Re-running `imakef`**

Once the set of options have been changed in the macros, it is useful to retain this set of options when `imakef` is run again. For this reason, `imakef` will check for the existence of a previous makefile. If one exists, it will re-use (in the new makefile) the set of macro definitions from the old one, plus any additional text up to a line marked “IMAKEF CUT”.

**11.9 Error messages**

`imakef` generates error messages of severities `Warning` and `Error`. Messages are displayed in standard toolset format.
Cannot have a makefile
The file specified on the command line is not one for which `imakef` can generate a makefile. `imakef` can only create makefiles for object files and bootable files.

Cannot open "filename" :reason
The file specified as the output file cannot be opened for writing by the program, for the reason given.

Cannot write linker command file
The linker command file cannot be opened for writing by the program.

Command line is invalid
An incorrect command line was supplied to the program. Check the syntax of the command and try again.

Error whilst reading
A file system error has occurred whilst reading the source.

#IMPORT references are illegal in configuration text
At the given line number in the file there is a reference to the `#IMPORT` directive, which is illegal for configuration source.

#INCLUDE may not reference a library
The `#INCLUDE` directive is being used to reference a file with the `.lib` extension.

#INCLUDE may not reference binary files
The `#INCLUDE` directive is being used to reference a file containing compiled code.

Incomplete compiler directive
At the given line number in the file there is an invalid compiler directive.

Library on PATH "pathname" also exists in the current directory
A library with the specified name has been found on the current search path and in the current directory.

Malloc failed
The program has failed while trying to dynamically allocate memory for its own use. Try using a transputer board with more memory. If the program is being run on the host it may be possible to increase the memory available using host commands.

Options are incorrectly delimited
The terminating bracket, which determines the options in a library build file, is missing at the given line number.
#SC references are illegal in configuration text

Applies to occam modules only.
At the given line number in the file there is a #SC directive, which is illegal in configuration source code.

#SC, #USE may not reference source files

Applies to occam modules only.
The directives #SC and #USE cannot be used to reference occam source code.

Source file does not exist

The referenced source file does not exist on the system.

Target is not a derivable file

The specified file cannot be generated by the toolset.

Tree checking failed - no output performed

The tree of files has been found to be invalid and unusable for generating makefile. This message always follows a message indicating what is wrong with the tree. The most common reason for this error is the presence of cyclic references in the source.

"filename" unknown/illegal file reference

A compiler directive is attempting to reference the wrong type of file.

Writing file

A host system error occurred while the file was being written.
11.9 Error messages
This chapter describes the memory map tool imap. The tool takes the text output from the toolset compiler, linker and collector and gives the absolute addresses of the static variables and functions. The chapter begins with an introduction to imap and explains the command line syntax. imap's output is described in some detail and an example is given. The chapter ends with a list of error messages.

12.1 Introduction

The imap tool takes as input memory map files output by the compiler, linker and collector. Command line options for these tools enable the user to specify that a memory map file is to be produced. imap collates the information from the different source files and puts it in a format suitable for output on the display screen. Alternatively the output from imap can be redirected to another output file as the user wishes. Memory maps may be generated for both single and multiprocessor transputer programs.

imap is invoked by supplying it with the name of a map file produced by the collector. The tool will automatically determine the names of map files produced by the linker and compiler, provided the naming convention for extensions has been adhered to, see section 12.2.1. Each tool generates a different level of information:

- **Collector:** For each process on each processor, memory locations of code, static, heap, stack, invocation stack and vector space are listed.
- **Linker:** For each process the offset in memory for code and static for individual modules which make up the process are listed.
- **Compiler:** For each module listed in the linker output file the offset in memory for individual static items, procedures and functions are listed.

Where a particular category of information is not applicable to a language, this field will be left blank. occam programs for instance do not use heap, so obviously such details are not generated for occam.

Where the output files from the compiler and linker cannot be opened or parsed properly imap will insert a warning at the appropriate point in the output.

The operation of the map tool in terms of standard toolset file extensions is shown below. Output is sent to standard out, which is usually set to the display screen.
12.2 Running the map tool

To invoke the map tool use the following command line:

\[ \texttt{imap filename \{ options \}} \]

where: \textit{filename} is the name of the file containing the map output from the collector \texttt{icollect}. If there is no extension given, \texttt{.map} is assumed. Otherwise the file name is taken as given.

\textit{options} is a list of the options given in Table 12.1

- Options must be preceded by ‘\texttt{-}\’ for UNIX-based toolsets and ‘\texttt{/}\’ for MS-DOS and VMS based toolsets.
- Options may be entered in upper or lower case and can be given in any order.
- Options must be separated by spaces.

Only one filename may be given on the command line.

If no arguments are given on the command line a help page is displayed giving the command syntax.

**Examples of use:**

\texttt{imap myprog}

\texttt{imap myprog.map}

Both the above examples will cause \texttt{imap} to read the file \texttt{myprog.map}, generated by the collector.
Table 12.1 imap command line options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Displays the list of symbols produced by the linker, including those symbols the linker identifies as not being used. This option will not override the 'R' option if it is used.</td>
</tr>
<tr>
<td>I</td>
<td>Displays progress information as imap processes information from the input files, such as the filenames of files as they are opened and closed.</td>
</tr>
<tr>
<td>O filename</td>
<td>Specifies an output file.</td>
</tr>
</tbody>
</table>
| R | This option reduces the amount of detail generated by imap in two ways:  
- the Module memory usage table only displays details for user modules i.e. 'USER' and 'SHARED_USER' processes.  
- the Symbol table excludes those symbols containing a '%' character in their name. Such symbols are normally internal symbols e.g. C runtime library symbols. |
| ROM hex offset | This option is only applicable to, and must be specified for, code targeted at ROM. It enables a hexadecimal offset to be specified which represents the start address of the code in ROM. This offset will be added to the start address of any code which is to run in ROM, in imap's output. |

12.2.1 Source files required by imap

Three different types of source file are read by imap and should therefore be made available. The files are in fact memory maps generated by the compiler, linker and collector. The appropriate command line option must be specified on each tool's command line including a filename for the map produced. The filename specified by the user must have the appropriate extension as indicated in table 12.2.

Table 12.2 Files extensions for imap source files

<table>
<thead>
<tr>
<th>Extension</th>
<th>File description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.mxx</td>
<td>Map file output by the compiler. The characters 'xx' are determined by the 2nd and 3rd characters of the extension given to the compiler object file. For example if the compiler object file takes the default extension .teo, the information file is given the extension .meo.</td>
</tr>
<tr>
<td>.dxx</td>
<td>Map file output by the linker. The characters 'xx' are determined by the 2nd and 3rd characters of the extension given to the linker object file. For example if the linker object file takes the default extension .lku, the information file is given the extension .dku.</td>
</tr>
<tr>
<td>.map</td>
<td>Map file output by the collector.</td>
</tr>
</tbody>
</table>
12.2.2 Re-directing imap's output

imap's output goes to standard out by default. To redirect it to an output file, use the 'o' option and specify an output filename.

12.3 Output format

This section describes the format of the memory map produced by imap. An example output is given in section 12.4.

If the imap tool cannot find a linker or compiler output file, it will insert a warning message in place of the missing information. It will not produce a warning if the process or module comes from a library (such as the system process library).
12 imap - memory mapper

12.3.1 imap memory map structure

- All processors used are listed. Details for each processor are as follows:
  - Processor name – if specified by the user in a configuration data file.
  - Processor Id. – a unique number which is assigned by the collector. These numbers start from zero, and increase by one for each processor.
  - Processor type e.g. T400, T805 etc.
  - A list of processes, (in the same order as the collector output file). The following details are given for each process as appropriate:
    - Process Id. – a three digit number assigned by imap. Process numbers start at 000 and are incremented by 1 for each new process.
    - Process priority – HIGH or LOW
    - Process type – USER; SHARED_USER; INITSYSTEM; SYSTEM or OVERLAID_SYSTEM. See table 12.3.
    - Process name, if specified by the user.
    - A list of linked units or a library from which the process is made. For each linked unit or library the following details are included:
      - Name of the linked unit or library
      - The file offset in memory, expressed as a decimal number.
      - The offset from the start of the linked unit or library, at which code for that process begins, (expressed as a decimal number). In a linked unit this will usually be a very small number, pointing to just after the header, whereas in a library, where the code is selected from a number of related chunks of code, the offset may point to anywhere within the library.
      - A list of modules that make up the unit. The list is in the same order as the linker output file. Details include:
        - Module Id. – a three digit module number assigned by imap.
        - TCOFF object filename.
        - Name of the source file from which the object was generated.
  - A table of the memory blocks allocated to user processes. See 12.3.3.
  - A table of the code and static memory blocks used by individual modules, including the section of memory that each block represents. See 12.3.4.
  - A table of the memory blocks that non-user processes use. See 12.3.5.
  - A table of symbols used by all of the processors. See 12.3.6.
12.3.2 Process types

<table>
<thead>
<tr>
<th>Process type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INITSYSTEM</td>
<td>A process used in the initialization of the transputer network.</td>
</tr>
<tr>
<td>OVERLAID_SYSTEM</td>
<td>System process which is overwritten by other processes after it has been used.</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>A process used in the initialization and running of the network.</td>
</tr>
<tr>
<td>USER</td>
<td>A user process.</td>
</tr>
<tr>
<td>SHARED_USER</td>
<td>A user process whose code can be used by more than one process.</td>
</tr>
</tbody>
</table>

Table 12.3 Process types

12.3.3 User processes

The table headed with "User processes" gives the start and end addresses and lengths of the various blocks of memory used by the user processes for that processor. The table is ordered by start address and is structured as follows:

- Process number or ‘All’ if it is the parameter data block, which is not associated to just one process.
- Memory block type – stack; overhd; code; heap; static or param. See table 12.4.
- Start address in hexadecimal.
- End address in hexadecimal.
- Length in decimal.

<table>
<thead>
<tr>
<th>Block type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stack</td>
<td>Used for workspace</td>
</tr>
<tr>
<td>overhd</td>
<td>Used for invocation stack</td>
</tr>
<tr>
<td>code</td>
<td>Used for code</td>
</tr>
<tr>
<td>heap</td>
<td>Used for heap</td>
</tr>
<tr>
<td>static</td>
<td>Used for static data</td>
</tr>
<tr>
<td>param</td>
<td>Used for the parameter data block</td>
</tr>
<tr>
<td>vector</td>
<td>Used for vector space (for Occam programs)</td>
</tr>
</tbody>
</table>

Table 12.4 Memory block types

12.3.4 Module memory usage

The table headed with “Module memory usage” gives the memory areas that are used by each module for code or static data. The table is ordered by start address and has the following format:
• Process i.d.
• Module i.d.
• Type (code or static)
• Name of the section that the area belongs to
• Start address in hexadecimal.
• End address in hexadecimal.
• Length of the area in decimal.

Examples of section names are pri\textbase and text\textbase for code, and static\textbase for static data.

If the 'R' command line option is used only details of user processes are shown.

12.3.5 Other processes
The table headed with "Other processes" is the same as the "User processes" table but for all the non–user processes. This table will not include an entry for the parameter data block.

12.3.6 Symbol table
The symbol table is alphabetically ordered by symbol name and gives the following information:

• Symbol name.
• Processor Id.
• Process Id.
• Module Id.
• Start address associated with symbol (in hexadecimal).
• Symbol type (see below).

The type field of the symbol table is either taken directly from the compiler map file, or is created by imap. In the latter case, the field will be enclosed in parentheses. This information is based on which section the symbol comes from. Refer to the compiler documentation for the meaning of items in this field that aren't enclosed in parentheses.

Note: command line options can be used to extend or limit the amount of symbol information generated. Normally imap only gives details of symbols used by the program; the 'A' option instructs imap to include unused symbols in the list. The 'R' option prevents details of internal symbols, such as those used by the runtime libraries, being listed.
12.4 Example

The following example, for a single processor program, was generated by the command:

```plaintext
imap test -r
imap test /r
```

**Memory map for 'test1'

---

**Map for processor 0 (T800)

---

**List of processes

---

P:000 - LOW priority INITSYSTEM process: 'Init.system'
From 'sysproc.lib' (offset 4969)

P:001 - LOW priority SYSTEM process: 'System.process.a'
From 'sysproc.lib' (offset 13391)

P:002 - HIGH priority SYSTEM process: 'System.process.b'
From 'sysproc.lib' (offset 28774)

P:003 - LOW priority USER process:
From 'testt800.lku' (offset 2)

M:001 - Module 'testt800.tco' from 'testt800.c'
M:002 - Module '/inmos/prod/d4214b/libs/centry.lib' from 'tmp.occ'

Figure 12.3 imap example, screen 3 of 3
12.5 Error messages

This section lists each error message that can be generated by the memory map tool. Messages are in the standard toolset format which is explained in appendix A.

All open files are closed when an error is found and the tool halts without producing a map.

12.5.1 Serious errors

Filename input file cannot be parsed properly

The named file cannot be read by imap.

Cannot open collector's output file for reading

The collector map file specified on the command line cannot be found. Check that the extension used for the collector map file is in the correct format. See section 12.2.

Cannot open output file for writing

The output file cannot be opened for writing. May indicate a disk space problem or some other host system error.

Error parsing command line

The command line has the wrong syntax or a non-existent option has been specified.

Must specify input file

An input file must be specified.

Only single output filename allowed

More than one output filename has been specified.

Only single ROM offset value allowed

More than one ROM offset has been specified.

12.5.2 Fatal errors

Filename internal data structure failure or file corrupt

A source file used by imap has referenced something which cannot be found. This can occur when redundant map files are read by imap in error.

72 TDS 367 01 March 1993
12.5 Error messages

Filename out of heap space

There is not enough heap space to generate the memory map.

Unexpected end of file

A source file, read by `imap` has been corrupted. Regenerate compiler, linker and collector map files.
This chapter describes the host file server \texttt{iserver} which loads application programs onto transputer networks and provides runtime access to the host.

This document describes version 1.5 of the server. This is completely compatible with earlier versions but provides greater flexibility in the way transputers are accessed. In particular, the server can access transputer systems connected to a computer network (e.g. via Ethernet).

A summary of the new features of this version appears in Section 13.9.

\section*{13.1 Introduction}

The host file server \texttt{iserver} provides three functions:

- Loading bootable programs onto transputer systems.

- A runtime environment for application programs, giving access to host services (e.g. file and terminal i/o).

- Controlled access to transputer systems; multiple users in a computer network can request a specific transputer system or a particular type of transputer. Access to each transputer system is granted to one user at a time for as long as required.

\section*{13.2 Loading programs}

Before a program can be loaded into a transputer network it must be compiled and linked. Multi-transputer programs must also be configured for the transputer system they are to run on. The program is made bootable with the collector tool, \texttt{icollect}. The bootable file will generally have a \texttt{.btl} file extension.

\section*{13.3 Host interface}

Generally, transputer applications communicate with the host file server using the standard i/o libraries for the language being used. The library calls available and their parameters will be documented in the relevant language manual.

The communication with the host is based on a protocol, defined in appendix \texttt{C}. This protocol is used by the C, FORTRAN, and occam run time libraries to communicate with the host.
13.4 Access to transputer networks

Previous versions of the server required different code (and, therefore, a different executable) for every type of host interface. This version of the server provides support for all types of link interface in a single program. This means that when the server is run, it must be told what transputer systems are available and which type of interface to use for each.

User links

Each transputer system can be thought of as being connected to the host by a user link. User links are given descriptive names (known as capabilities) which are used by the server to find a suitable transputer system. Programs may be loaded onto transputer systems down user links, whilst operating system services are provided to the programs by communicating with the host file server via the user link. The names of the available user links, and the way in which the transputers are accessed, are defined in a connection database file.

More detail on user links, the connection database file, and accessing transputer networks is provided in section 13.7.

The session manager

The iserver guarantees unique access to a transputer system while it is running. The system is released when the server terminates. Often, the same resource needs to be used to run several programs (or run one program several times). For example, after running a program, it may be necessary to use the debugger — it would not be very useful if another user had started using the transputer between the program failing and the debugger starting.

The server's session manager allows access to a resource to be guaranteed for as long as required. The session manager is started with the 'SM' option and provides a simple command line interface. All the normal host operating system commands can be used as well as the iserver and session manager commands.

More detail on using the session manager are given in section 13.6.

13.5 Running the iserver

To run the host file server use the following command line:

```bash
iserver {options}
```

where: options is a list of one or more options from Table 13.1.

If iserver is invoked with no options, help information is displayed, briefly explaining the command line arguments.

Some parameters can also be provided by the environment variables which are described in Section 13.5.2. These can be overridden by values provided on the command line.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

<td>Invokes the session manager interface.</td>
</tr>
<tr>
<td><strong>SP n</strong></td>
<td>Sets the size of memory to peek on Analyse to n Kbytes.</td>
</tr>
<tr>
<td><strong>SR</strong></td>
<td>Resets the root transputer and its subsystem.</td>
</tr>
<tr>
<td><strong>SS</strong></td>
<td>Serves the link, i.e. provides host system support to programs communicating on the host link.</td>
</tr>
<tr>
<td><strong>ST</strong></td>
<td>All of the following command line is passed directly to the booted program as parameters.</td>
</tr>
</tbody>
</table>

Options must be preceded by '-' for UNIX based toolsets.
Options must be preceded by '/' for non-UNIX based toolsets.
There must be at least one space between options. The case of letters in the parameters are not significant.
Options may be in any order, except that no further options may appear after ST.
Option 'SB filename' is equivalent to 'SR SS SI SC filename'.

Table 13.1 Host file server options

### 13.5.1 Examples of use

**UNIX based toolsets:**

```plaintext
icc hello
ilink hello.tco -f cstartup.lnk
icconf hello.cfs
icollect hello.cfb
iserver -sb hello.btl -se
```

**MS–DOS/VMS based toolsets:**

```plaintext
icc hello
ilink hello.tco /f cstartup.lnk
icconf hello.cfs
icollect hello.cfb
iserver /sb hello.btl /se
```

In this example `iserver` is executed to load and serve the bootable file `hello.btl` and to terminate on error. The example also shows the steps for compiling, linking, configuring and making the bootable file.

**Note:** this example assumes that the environment variable `TRANSPUTER` has been set to the name of the user link to be used.
13.5.2 Server environment variables

The server may obtain some parameters by inspecting environment variables. The following names are used:

- **TRANSPUTER** Defines the capability (user link name) to be used by the server. May be overridden by the **SI** option.
- **ICONDB** Defines the name of the connection database file used by the server.
- **ISESSION** Defines the name of the session manager configuration file. The default is ‘session.cfg’.

13.5.3 Loading programs

Before a program can be loaded onto a transputer network it must be compiled, linked and made bootable.

**Running a program using the iserver — option SB**

The name of the file containing the bootable program is specified using the ‘SB’ option. This resets the board and then copies the contents of the bootable file to the user link. If the file cannot be found an error is reported. When the program has been successfully loaded the server then provides host services to the program.

**Note:** Using the ‘SB’ option is equivalent to using the **SR, SS, SI** and **SC** options together.

**Sending data down a user link — option SC**

To send data down a user link, or to load a program onto a board without resetting the root transputer, use the ‘SC’ option — this simply copies the contents of the specified file to the user link. This should only be done if the transputer is running a program that can interpret the data sent down the link, or has already been reset. To reset the transputer subsystem use the ‘SR’ option.

**Running programs which do not use the server**

To terminate the server immediately after loading the program use the ‘SR’ and ‘SC’ options together. This combination of options resets the transputer, loads the program onto the board, and terminates the server — the program on the transputer will continue running. This can be used to run a program which does not need to use the server facilities. If the program on the transputer attempts to access the server then it will deadlock until the server is run with the ‘SS’ option.

**Note:** single transputer programs built with the collector’s ‘T’ option cannot be run in this way as the loader uses the server to read the value of the environment variable **IBOARDSIZE**. Configured programs (and programs built with the collector’s ‘T’ and ‘M’ options) will perform no communication with the host other than that specified in the user’s program.
Analyzing a transputer network — option SA

To load a board in analyze mode, for example when you wish to use the debugger to examine the program's execution, use the 'SA' option to dump a section of the transputer's memory (starting from MOSTNEG INT). The default amount of memory to dump is 8 Kbytes, but this can be overridden with the 'SP' option. The data is stored in an internal buffer which can be read by the idump tool when programs that use the root transputer are to be debugged.

Terminating the server

When the program sends a terminate command to the server (or some serious error occurs) the server will terminate if the session manager is not being used. If an error occurred an error message will be printed. If the session manager interface is being used, then control will return to the session manager.

13.5.4 Supplying parameters to a program

Any parameters on the command line following the 'ST' option are passed as parameters to a booted program. This includes parameters that would normally be interpreted as iserver parameters. In addition, any text on the command line that is not recognized as a server parameter is also passed to a booted program.

13.5.5 Specifying the transputer resource — option SL

To specify the transputer resource to be used a capability name must be specified. The server may be given the capability on the command line using the 'SL' option.

The capability may also be specified by the environment variable TRANSPUTER. This variable is overridden by a capability specified by the 'SL' option.

The SK option can be used to specify how frequently the server should retry if the requested resource is not available; by default it does not retry.

13.5.6 Terminating on error — option SE

When debugging programs it is useful to force the server to terminate when the subsystem's error flag is set. To do this use the 'SE' option. This option should only be used for programs written entirely in OCCAM and compiled in HALT system mode. If the program is not written entirely in OCCAM then the error flag may be set even though no error has occurred.

13.5.7 Terminating the server

To terminate the server press the host system break key. The server will either then terminate, returning to the host operating system prompt, or return to the session manager interface prompt if the server was invoked with the 'SM' option.
13.5.8 Specifying the session manager configuration file

The session manager configuration file contains `iserver` commands for use by the session manager and may be customized for personal use.

The file is given by the environment variable `ISESSION`. If `ISESSION` is not set, then the filename `session.cfg` is used.

13.6 Using the session manager interface

The session manager provides a mechanism for guaranteeing unique access to a transputer system for as long as is required. Once the server terminates, or the system is released from within the session manager, access to the same system is no longer guaranteed.

13.6.1 Session manager commands

The session manager has a simple command line interface. There are a number of commands for managing the session such as `open` to select the transputer resource to be used, and `exit` to terminate the session. A complete list of session manager commands is given in table 13.2.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iserver parameters</code></td>
<td>Run as server to load network and provide host services. This command has most of the same options as the normal <code>iserver</code> command (except, of course, 'SI' and 'SM').</td>
</tr>
<tr>
<td><code>source filename</code></td>
<td>Read commands from a file</td>
</tr>
<tr>
<td><code>open capability</code></td>
<td>Release any held system and open a session with the named capability.</td>
</tr>
<tr>
<td><code>options parameters</code></td>
<td>Specify command line parameters to <code>iserver</code> command.</td>
</tr>
<tr>
<td><code>show</code></td>
<td>List user-defined commands.</td>
</tr>
<tr>
<td><code>help</code></td>
<td>List internal and user-defined commands.</td>
</tr>
<tr>
<td><code>exit</code> or <code>quit</code></td>
<td>Release any held system and exit the session manager.</td>
</tr>
<tr>
<td><code>user command</code></td>
<td>A user-defined command.</td>
</tr>
<tr>
<td><code>any other command</code></td>
<td>Any other command is passed directly to the host operating system.</td>
</tr>
</tbody>
</table>

Table 13.2 Session manager commands

13.6.2 The options command

The `options` command allows a set of standard options for the session manager's `iserver` command to be defined. Any parameters to the `options` command
are saved and added to any following iserver command. See the examples in sections 13.6.3 and 13.6.4.

With no parameters, the options command displays the parameters which are currently set. To remove parameters which have previously been set with the options command, use an empty string as the parameter, i.e.

```
options ""
```

13.6.3 The iserver command

The command iserver starts the server, from within the session manager, to load code onto the transputer system and provide host services to it. This command can be followed by any of the command line options described in section 13.5 (except 'SL' and 'SM' which are ignored). This allows programs to be run repeatedly on the same transputer system. When the program running on the transputer terminates (whether due to a normal termination, an error condition, or a user interrupt) control is returned to the session manager, without releasing the transputer system.

**Note:** the options to the session manager iserver command must be preceded by the appropriate option character as defined in table 13.1.

When an iserver command is executed, either directly or via a user-defined command, the parameters are built up from 3 parts in the following order:

1. The parameters supplied with the options command.
2. The parameters entered on the command line by the user.
3. The parameters from the command definition (if a user-defined command).

**Example (UNIX based systems):**

If the following commands are executed in the session manager:

```
# options -sb ika.btl
# iserver -si 42 tako.dat
```

Then the following iserver command line is generated:

```
iserver  -sb ika.btl:  -si 42 tako.dat:  Parameters from the parameters -from options command:  Parameters from the command line:
```

**Example (MS-DOS/VMS based systems):**

If the following commands are executed in the session manager:

```
# options /sb ika.btl
# iserver /si 42 tako.dat
```
Then the following `iserver` command line is generated:

```
iserver /sb ika.btl /si 42 tako.dat
```

Parameters from the command line

13.6.4 User-defined commands

In addition to the built-in commands of the session manager, new commands can be defined by the user. These commands define a set of parameters to be passed to the session manager `iserver` command, giving a shorthand for regularly used commands.

New commands are defined in the session manager configuration file, named in the environment variable `ISESSION`. The commands are defined as a set of parameters to the session manager’s `iserver` command.

The format of the file is simple. Each command occupies a single line. The command name is the first word on the line. The rest of the line are the parameters to the `iserver` command that is to be substituted for the user-defined command.

As an example, suppose a program called `mytool` is normally booted onto a transputer with the `SE` and the `SB` options followed by user parameters for the tool. The normal `iserver` command line might look something like this:

```
iserver -se -sb /usr/tpbin/mytool.b8h parameters (UNIX)
iserver /se /sb /usr/tpbin/mytool.b8h parameters (MS-DOS/VMS)
```

To simplify this inside the session manager, the following lines would be put in the session manager configuration file:

```
mytool -se -sb /usr/tpbin/mytool.b8h (UNIX)
mytool /se /sb /usr/tpbin/mytool.b8h (MS-DOS/VMS)
```

Then, if the command `mytool parameters` is entered on the session manager command line it will be replaced with the command:

UNIX based systems:

```
iserver parameters -se -sb /usr/tpbin/mytool.b8h
```

Parameters from the command line

Parameters from the command definition

MS-DOS/VMS based systems:

```
iserver parameters /se /sb /usr/tpbin/mytool.b8h
```

Parameters from the command line

Parameters from the command definition
The server command line is built up as described above in section 13.6.3 so, if some extra parameters are defined with the options command they will be included as well. For example, the command sequence:

UNIX based systems:  
options -si  
mytool parameters  

MS-DOS/VMS based systems:  
options /si  
mytool parameters  

Would cause the following iserver command to be generated:

UNIX based systems:  
iserver -si parameters -se -sb /usr/tpbin/mytool.b8h  

MS-DOS/VMS:  
iserver /si parameters /se /sb /usr/tpbin/mytool.b8h  

Running the debugger from the session manager

One important use of user defined commands in the session manager is to allow the debugger to be run. This is done by defining a command such as the following in the session manager configuration file.

idebug -se -sb /usr/local/DS214/itools/idebug.btl  

(MS-DOS/VMS)

The exact form of this command will depend on which toolset is being used and the type of program being debugged. For more details on idebug command line options, see chapter 4.

13.6.5 Host OS commands

If a command is not one of the session manager's internal commands and not a user-defined command then it is passed to the host's operating system for execution.

13.7 Connecting transputers to computer networks

Transputer systems may be connected to the host computer in a number of ways. For example, they may be connected directly to the host via a board such as the IMS B008 motherboard, or via Ethernet using an IMS B300 TCPlink box.¹

Each connection, however implemented, is treated in the same way. Programs can be loaded onto a transputer system via any of these connections and that program can then gain access to host facilities and communicate with the user via the same connection. Each of these connections is known as a user link.

13.7.1 Capabilities

User links are identified to users (and tools) by name. Each user link has one or more names, known as capabilities — the names should be chosen to indicate to

¹. It is also possible to remotely access a transputer directly connected to another (remote) host. This requires the host connection server (HCS) to be running on the remote host — currently the HCS software is only available for PCs.
a user what type of transputer system is connected to that user link. Examples of
capability names that might be used are B008, T801+2MB, or Grid:10x10.

If access to a transputer system is desired, one of the capability names of a user
link is given to the iserver. If a user link of that name is free then unique access
to that user link is granted until the server terminates. If the session manager inter­
face of the server is used (see Section 13.6), then unique access to the user link
can be maintained for as long as required. If the capability specified is not unique
then the iserver searches for the first free user link on the local machine with that
capability. If that capability is not available, remote machines are then searched.
For this reason each user link will normally have several capabilities, at least one
of which will be unique in the network.

Figure 13.1 shows an example computer network with four user links. Each user
link has several capabilities. If a specific user link is to be used then the capability
USERLINK1, USERLINK2 etc. should be used. If that user link is free unique
access to it will be given. If all that is required is a 32 bit transputer (to run a tool,
for instance) then the capability 32bit-Transputer could be used; connection
to either of user links 3 or 4 could then be made, assuming that one of them is free.

When the iserver is run it is given the name of a capability with the ‘SL’ option
or the environment variable TRANSPUTER. The server finds the information it
needs to access that transputer network from the connection database file.

13.7.2 The connection database

Each transputer system available is described in the connection database file. The
iserver, when given the name of a transputer system, uses the connection data­
basis to determine how to access that system. The name of the connection data­
base file is defined by the environment variable ICONDB.

The connection database is a text file which contains a description of all the avail­
able capabilities. In a PC development system, for example, the connection data­
basis may contain only a single entry — the transputer board which is installed in
the PC. In a multi-user development environment, such as a networked Sun
workstation, the database may contain a number of capabilities representing...
transputer links connected directly to the host or accessible via Ethernet. In this case the connection database will be set up by the system administrator.

There may be several entries in the connection database with the same capability name. In this case, when a user runs iserver specifying this capability, the first system with that capability name which is not already in use will be allocated to the user.

The connection database must exist for iserver to be able to access a transputer. The server uses the environment variable ICONDB to locate the connection database file.

Examples and further details of the contents of the connection database are given in section 13.8.

13.7.3 Using a specific node

It is possible to request that a capability on a specific network node is used (note that 'node' in this context may be an IMS B300 Ethernet interface). To do this the character '@' is added after the capability name, followed by the name of the node. When this is done the named node is contacted directly. If the specified capability is not free on that node then the request will fail.

For example, to use the capability T4-torus on the node pwllheli the name T4-torus@pwllheli would be specified to the server.

The special name localhost is defined as being the the local host (alternatively, the local host's name may be used directly). If the local host is specified then only local user links may be used. If no suitable user link is found locally the request will fail.

13.8 The connection database

This section gives more detail about the connection database file that provides information to the server about the available transputer networks.

13.8.1 Connection databases

A connection database file must be available on your host before you can gain access to any user links. The connection database describes the transputer systems available on your network. The format of the connection database file is described below, in section 13.8.2.

In a single-user system such as a PC-compatible development system, there may only be a single entry in the connection database file – this will describe the transputer board installed in the PC. A typical entry for an IMS B008 board in a PC might look like this:

```
|B008|T|localhost|#150|b004| |B008 with 3 x T805|
```

March 1993
In a larger development environment, there may be many entries describing all the transputer systems in the entire network of development systems. In this case, the connection database file will usually be created and managed by the system administrator.

**Capability names**

There may be a number of different user links with the same name so that similar transputer systems can have the same capability. For example, all the user links which are connected to transputers which can run transputer based tools could be given the capability `ToolHost`.

Similarly, there may be more than one entry for each transputer system in order to give multiple names to the same resource. This allows a transputer network with a 30MHz T805 transputer, for example, to be described with the capabilities `ToolHost` (for user who want to use any transputer that can run transputer based tools) and `T805-30` (for those who need to use that specific type of transputer).

### 13.8.2 Connection database format

Connection database files are ASCII text files. It can contain four types of line:

- **Blank lines** — these are ignored.
- **Lines starting with a '#' character** are comment lines, and are ignored.
- **Lines starting with a 'I' character** are record lines, containing connection data.
- **Lines starting with a '*' character** are continuation lines, used when a record line will not conveniently fit on one line.

Records in the database are made up of eight fields, in a fixed order. Fields are separated by a 'I' character. Records may be broken over a number of lines if required, but may only be broken between fields. In this case a '*' character is used as the field separator, and must appear at the end of the line to be continued, and as the first character on the continuation line. The characters 'I' and '*' are not permitted within any field. Trailing spaces in a field are ignored.

The fields are shown in Table 13.3. There are two field types, *String* and *Boolean*. A *String* is one or more ASCII text characters and a *Boolean* is a single ASCII character, either 'f' or 'F' for *false* or 't' or 'T' for *true*.

13.8.3 Example connection databases

PC development system

The first example shows how 2 PC add-in boards in the same system could be described. Each board has two names: a common name (B008) to allow a user to access whichever user link is available, and a unique name to enable the user to specify which transputer system they wish to use (T400 or T805).

```plaintext
# The following resource describes a B008 with a T400.
# The link device is at address #150.

[T400 | Tlocalhost|#150|b004]| |B008 board with T400 + 2MB|
[B008 | Tlocalhost|#150|b004]| |B008 board with T400 + 2MB|

# The following resource describes a B008 with a T801.
# The link device is at address #200.

[T805 | Tlocalhost|#200|b004]| |B008 board with T801 + 2MB|
[B008 | Tlocalhost|#200|b004]| |B008 board with T801 + 2MB|
```
Sun workstation

This example shows how the various boards that can be connected to a Sun workstation directly, can be described in a connection database file.

```bash
# Sample connection database.
# The device names and addresses supplied are the default names
# and/or addresses suggested in the installation section of the
# board's manual.

# The following resource allows access to a B011 connected to this
# host. The resource name is "B011" and the device is accessed
# at address 0x800000.
[B011 |T|localhost|0x800000|b011]| |Description of board|

# The following resource allows access to a B014 connected to the
# host. The resource name is "B014" and the B014 device driver is
# accessed via "/dev/bxiv0".
[B014 |T|localhost|/dev/bxiv0|b014]| |Description of board|

# The following resource allows access to a B016 connected to the
# host. The resource names are "B016-0" to "B016-3" and the B016
# device drivers are accessed via "/dev/bxvi0" through to
# "/dev/bxvi3".
[B016-0 |T|localhost|/dev/bxvi0|b016]| |Description of board|
[B016-1 |T|localhost|/dev/bxvi1|b016]| |Description of board|
[B016-3 |T|localhost|/dev/bxvi2|b016]| |Description of board|
[B016-4 |T|localhost|/dev/bxvi3|b016]| |Description of board|

IMS B300

The following example shows how four transputer systems available via Ethernet
could be described.

```bash
# Connection database for an IMS B300 with the node name 'billy'

# A T425 connected to link 2 of the B300
|HOSTLINK0 |T|billy|2|tcp|T425+1M|
|TA |T|billy|2|tcp|T425+1M|
|T425 |T|billy|2|tcp|T425+1M|

# A T805 connected to link 3 of the B300
|HOSTLINK1 |T|billy|3|tcp|T805+2M|
|TA |T|billy|3|tcp|T805+2M|
|T805 |T|billy|3|tcp|T805+2M|

# Another T805 connected to link 0 of the B300
|HOSTLINK2 |T|billy|0|tcp|T805+2M|
|TA |T|billy|0|tcp|T805+2M|
|T805 |T|billy|0|tcp|T805+2M|

# A small network connected to link 1 of the B300
|HOSTLINK3 |T|billy|1|tcp|T800+4M + T805+2M + T222+60K|
|TA |T|billy|1|tcp|T800+4M + T805+2M + T222+60K|
|T800 |T|billy|1|tcp|T800+4M + T805+2M + T222+60K|
```
13.9 New server features

This section summarizes the main differences between version 1.5 of the iserver and previous versions.

The new features are:

- The addition of a session manager user interface.
- A connection manager has been added, and capability names are used instead of link names. There is no longer a default name.
- Some new command line options have been added.
- User interrupt behavior has changed.
- Exit codes have changed.
- New error codes have been added.
- Stream identifiers are validated.
- Support for record structured files has been added.

These changes are described in more detail in the following sections.

13.9.1 Session manager

This is a simple user interface that provides control of access to shared transputer resources. It will provide unique access to a specified transputer resource (if available) for as long as required. See section 13.6.

13.9.2 Connection manager

The connection manager provides transparent access to both remote and local transputer resources. Resources are identified by a "capability name" and, optionally, the name of the host to which the resource is connected. See section 13.7.

13.9.3 New command line options

Three new command line options have been added:

- SK  Retry the connection at intervals.
- SM  Invoke the session manager interface.
- ST  All arguments which follow are not iserver arguments and will be passed to the application. Note that this is a significant change to the way that the iserver parses its command line. Existing command files or shell scripts may need to be changed.

13.9.4 User interrupt

Behavior on user interruption depends on how the server is being run. If the session manager interface is being used, then the server returns to the session
manager interface. If the session manager is not being used then the server terminates.

13.9.5 Exit codes

This version of the iserver makes it possible to distinguish between the various causes of termination of the server, such as user break, error flag set etc. Appendix C provides full details of the exit codes.

13.9.6 Error codes

Server operations now return a range of error codes to indicate the cause of a failure. Checks are now made to ensure that operations are supported, a particular transputer system is available etc.

Appendix C provides details of iserver error codes.

13.9.7 Stream identifier validation

Checks have been added to the server to validate all stream identifiers. Earlier versions of the server assumed that a stream identifier would always be valid.

13.9.8 Record structured file support

Support for record structured files has been added for all supported hosts. Supported formats are formatted sequential, unformatted sequential, formatted direct and unformatted direct. See Appendix C for full details.

13.10 Error messages

A list of possible error messages which iserver may produce follows. In some cases, these messages may be followed by an extra message giving additional information; these are listed below in section 13.10.1.

Aborted by user

The user interrupted the server, by pressing [Ctrl-C] or [Ctrl-Break].

Boot filename is too long, maximum size is number characters

The specified filename was too long. number is the maximum size for filenames.

Cannot find boot file filename

The server cannot open the specified file.

Command line too long (at string)

The maximum permissible command line length has been exceeded. The overflow occurred at string.
Copy filename is too long, maximum size is number characters
The specified filename was too long. number is the maximum size for file-
names.

Error flag raised by transputer
The program has set the error flag. Debug the program.

Expected a filename after -SB option
The 'SB' option requires the name of a file to load.

Expected a filename after -SC option
The 'SC' option requires the name of a file to load.

Expected a name after -SL option
The 'SL' option requires a link name or address.

Expected a number after -SP option
The 'SP' option must specify the number of Kbytes to peek.

Failed to allocate CoreDump buffer
The 'SP' option was used but the server was unable to allocate enough
memory to allow the transputer's memory to be copied.

Failed to analyse root transputer
The link driver could not analyze the transputer.

Failed to reset root transputer
The link driver could not reset the transputer.

Reset and analyse are incompatible
Reset and analyze options cannot be used together.

Timed out peeking word number
The server was unable to peek the transputer.

Transputer error flag has been set
The program has set the error flag. Debug the program.

Unable to access a transputer
The server was unable to gain access to a link. This occurs when the link
address or device name, specified either with the SL option or the TRANS-
PUTER environment variable, is incorrect or does not exist. This message
will be followed by one of the messages listed below.
Unable to free transputer link
The server was unable to free the link resource because of a host error. The reason for the error will be host dependent.

Unable to get request from link
The server failed to get a packet from the transputer because of some general failure.

Unable to write byte number to the boot link
The transputer did not accept the file for loading. This can occur if the transputer was not reset or because the file was corrupted or in incorrect format.

13.10.1 Additional error messages
The following messages provide additional information to accompany error messages from the server.

: no environment variable ICONDB
There is no environment variable ICONDB.

: can't open connection database file [...]
The file specified in the environment variable ICONDB cannot be accessed.

connection database, file [...], at line [...]
→ premature end of file
The database file is corrupt, a record line is not complete.

connection database, file [...], at line [...]
→ premature end of file, looking for field {...}
The database file is corrupt. A record line is not complete; the field {...} does not exist.

connection database, file [...], at line [...]
→ expecting continuation character
Line [...] of the database file is corrupt. The record was not complete, a field is missing and there was no continuation indicating the record is continued on the next line.

connection database, file[...], at line[...]
→ expecting continuation character at start of line, looking for field {...}
Line [...] of the database file is corrupt. The previous line ended with a continuation character – a continuation was expected to start the current line.
connection database, file[...], at line[...]
-> can’t start a line with continuation, looking for field {...}
   Line [...] of the database file is corrupt. A record line started with a continuation character (it should start with a field separator). The {...} field was expected.

connection database, file[...], at line[...]
-> bad field separator, looking for field {...}
   Line [...] of the database file is corrupt; the field was illegal.

connection database, file[...], at line[...]
-> field {...} cannot be null
   Line [...] of the database file is corrupt. The field {...} contained a null value (this is illegal).

connection database, file[...], at line[...]
-> illegal boolean value, looking for field {...}
   Line [...] of the database file is corrupt. The field {...} should contain a boolean value.

connection database, file[...], at line[...]
-> illegal linkdev field – unknown method
   Line [...] of the database file is corrupt. The Linkdev field should contain a link method value.
This chapter describes the T425 simulator tool isim that allows programs to be run and tested without transputer hardware. The chapter explains how to invoke the tool and describes the simulator commands that allow the simulated program to be debugged interactively.

14.1 Introduction

The simulator can run any transputer program that would run on a single IMS T425 mounted on a normal transputer evaluation board and supported by a host running iserver. No transputer hardware is required.

Because the simulator runs the same code that would be loaded onto a real transputer, any program that runs satisfactorily in the simulator will run on an IMS T425. Because all 32-bit transputers are compatible at the source level, the same program can also be run on any INMOS 32-bit processor after recompiling for the correct processor type.

The simulator also provides a reduced set of debugging facilities similar to those of the debugger Monitor page. Additional features provided by the simulator are the ability to set breakpoints at simulated transputer addresses and to single step the program. The program should be loaded into memory (using the \texttt{G}, \texttt{J} or \texttt{P} commands) before breakpoint debugging facilities are used. This ensures that breakpoints are not overwritten during the booting phase.

The simulator can also be used to familiarize new users with transputers and transputer programming, and as a teaching aid.

14.2 Running the simulator

To run the simulator use the following command line:

\texttt{isim program \{programparameters\} \{options\}}

where: \texttt{program} is the program bootable file.

\texttt{programparameters} is a list of parameters to the program. The list of parameters may follow the \texttt{isim `n`} option and parameters must be separated by spaces. See section 14.2.1.
options is a list of options from Table 14.1.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Batch mode operation. The simulator runs in line mode i.e. full display data is not provided. Commands are read in from the input stream e.g. the keyboard and executed. The commands are not echoed to the output stream e.g. the display screen, as they are executed.</td>
</tr>
<tr>
<td>BQ</td>
<td>Batch Quiet mode. The simulator automatically executes the program specified on the command line and then terminates. If an error occurs, the appropriate message will be displayed. The debugging facilities of the simulator are not available in this mode.</td>
</tr>
<tr>
<td>BV</td>
<td>Batch Verify mode. Similar to batch mode, except that the commands and prompts displayed when running the simulator in interactive mode are echoed to the output stream e.g. the display.</td>
</tr>
<tr>
<td>I</td>
<td>Displays information about the simulator as it runs.</td>
</tr>
<tr>
<td>N</td>
<td>No more options for the simulator. Any options entered after this option will be assumed to be program parameters to be passed to the program running on the simulator.</td>
</tr>
</tbody>
</table>

Table 14.1 isim options

14.2.1 Passing in parameters to the program

Program parameters can be passed to programs which are simulated on any host. Parameter passing is equivalent to running a transputer bootable program using iserver.

isim will normally parse the command line and any options it recognizes as its own will not be passed to the user program. In cases where options are required for a user program which clash with one of the isim options the ‘N’ option can be used. After the ‘N’ option isim ceases parsing the command line for its own options; the remainder of the command line is simply passed through to the user program.
14.2.2 Example of use

```bash
isim hello.btl
```

This invokes the simulator on the 'Hello World' program.

When first invoked the simulator enters the debugging environment. To start the program invoke the 'G' command. Then press [RETURN] in response to the "break point address" prompt. The program then runs until it completes successfully, a runtime error occurs, or a break point is reached. If an error occurs the processor halts, the error flag is set, and the program can be debugged using commands to examine memory and registers.

When invoked with the 'BQ' option (Batch Quiet) the simulator immediately runs the program and does not enter the debugging environment.

```bash
isim -bq hello.btl
isim /bq hello.btl
```

(UNIX based toolsets)

(UNIX based toolsets)

14.2.3 ITERM file

The simulator reads the ITERM file to determine how to control the terminal screen and to map a few simulator commands. The ITERM file must be defined in the host environment variable ITERM. See appendix D.

14.3 Monitor page display

The simulator Monitor page is similar to that of the debugger, which is described in chapter 4. Data displayed at the simulator Monitor page includes:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iptr</td>
<td>Contents of instruction pointer (address of the next instruction to be executed).</td>
</tr>
<tr>
<td>Wptr</td>
<td>Contents of workspace pointer.</td>
</tr>
<tr>
<td>Error</td>
<td>Status of error flag.</td>
</tr>
<tr>
<td>Halt On Error</td>
<td>Status of halt on error flag.</td>
</tr>
<tr>
<td>Fptr1</td>
<td>Pointer to the front of the low priority active process queue. If 'jump 0' breaks are enabled the letter B is displayed after the pointer value.</td>
</tr>
<tr>
<td>Bptr1</td>
<td>Pointer to the back of the low priority active process queue.</td>
</tr>
<tr>
<td>Fptr0</td>
<td>Pointer to the front of the high priority active process queue.</td>
</tr>
<tr>
<td>Bptr0</td>
<td>Pointer to the back of the high priority active process queue.</td>
</tr>
<tr>
<td>TPtr1</td>
<td>Pointer to the low priority timer queue. If the timer is disabled the letter X is displayed after the pointer value.</td>
</tr>
<tr>
<td>TPtr0</td>
<td>Pointer to the high priority timer queue.</td>
</tr>
</tbody>
</table>

Note: If Wptr contains the most negative address value, it will be described as 'invalid'. This normally means that no process is executing in the simulator (for example, the program may have become deadlocked).
The Monitor page also displays the last instruction executed, a summary of Monitor page commands, and, if an error has occurred, the cause of the error.

14.4 Simulator commands

All simulator commands are given at the Monitor page. Many of the commands are similar to those of the idebug Monitor page, however, there are a number of implementation differences. Full descriptions of the commands are given in the following sections.

14.4.1 Specifying numerical parameters

Some simulator commands require numerical parameters, such as addresses. These can be specified as simple expressions in decimal or hexadecimal format. Expressions can be the sum of two expressions, the result of subtracting one expression from another, or constants. Constants that can be specified are: Areg, Breg, Creg, Iptr, Wptr, decimal constants, hexadecimal constants, or abbreviated hexadecimal constants.

Hexadecimal constants are specified using the prefix #. Abbreviated hex constants can be created by prefixing the sequence of hex digits with '8000...', which assumes the hexadecimal prefix '8000...'. For example, the abbreviation 'F8A' is interpreted as the hex number '8000F8A'.

14.4.2 Keys mapped by ITERM

Several commands for controlling the display are mapped to specific keys by the ITERM file, see appendix D. Key mappings for specific terminal keyboards can be found in the Delivery Manual.

HELP Displays help information.

REFRESH Re-draws the screen.

FINISH Quits the simulator.

PAGE UP Scrolls the current display.

PAGE DOWN Scrolls the current display.

▲, ▼ Scrolls the current display.
14.4.3 Command summary

Table 14.2 Simulator commands

14.4.4 Command descriptions

[A] — ASCII

This command displays a segment of transputer memory in ASCII format, starting at a specific address. If no address is given the default address Wptr is used. Specify a start address after the prompt:

(Start address (Wptr)) ?

Either press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by '#', or the short form '#h...h'.

72 TDS 367 01
March 1993
The memory is displayed in blocks of 13 rows of 32 ASCII bytes, each row preceded by an absolute address in hexadecimal. Bytes are ordered from left to right in each row. Unprintable characters are substituted by a full stop.

The ▲, ▼, [PAGE UP], and [PAGE DOWN] keys can be used to scroll the display.

### Breakpoints

Sets, displays, and cancels break points at specified memory locations or procedure calls. The program should be loaded into memory (using the [G], [J] or [P] commands) before this command is used to set breakpoints. (The [D] command may also be used prior to this command, to determine where to set breakpoints).

The command displays the Breakpoint Options Page:

```
Breakpoint Options Page
1) Set breakpoint at Address
2) Display breakpoints
3) Cancel breakpoint at Address
Select Option?
```

Options are selected by entering one of the single digit commands. The following prompts are displayed depending on the command selection:

<table>
<thead>
<tr>
<th>Command</th>
<th>Prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(break address) ?</td>
</tr>
<tr>
<td>3</td>
<td>(break address (ALL))</td>
</tr>
</tbody>
</table>

Pressing [RETURN] with no typed input in response to command 1 cancels the option; in response to command 3, it causes all breakpoints to be cancelled.

After each breakpoint command the user is returned to the simulator command prompt.

### Disassemble

The Disassemble command disassembles memory into transputer instructions. Specify an address at which to start disassembly after the prompt:

```
(Start address (Iptr)) ?
```

Either press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by '#', or the short form '#h...h'.

72 TDS 367 01            March 1993
The memory is displayed in batches of thirteen transputer instructions, starting with the instruction at the specified address. If the specified address is within an instruction, the disassembly begins at the start of that instruction. Where the preceding code is data ending with a transputer ‘pfix’ or ‘nfix’ instruction, disassembly begins at the start of the pfix or nfix code.

Each instruction is displayed on a single line preceded by the address corresponding to the first byte of the instruction. The disassembly is a direct translation of memory contents into instructions; it neither inserts labels, nor provides symbolic operands.

The [PAGE UP] and [PAGE DOWN] keys can be used to scroll the display.

**C** – Go

Starts the program, or continues running the program after a breakpoint or error has been encountered. The program will run until it completes successfully, sets the error flag, or reaches a break point.

To start the program, specify a break point address after the following prompt and press [RETURN]:

(break point address)

The default is not to set a break point.

**H** – Hex

The Hex command displays memory in hexadecimal. Specify the start address after the prompt:

(Start address (Wptr) ?

Press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by '#', or the short form 'h...h'. If the specified start address is within a word, the start address is aligned to the start of that word.

The memory is displayed as rows of words in hexadecimal format. Each row contains four words of eight hexadecimal digits, with the most significant byte first.

Words are ordered left to right in the row starting from the lowest address. The word specified by the start address is the top leftmost word of the display.

The address at the start of each line is an absolute address displayed in hexadecimal format.
278 14.4 Simulator commands

\[ \text{Inspect} \]

Displays a portion of memory in any \textit{occam} type – as defined in the ‘\textit{occam 2 Reference Manual}’.

The Inspect command can be used to inspect the contents of an entire array.

Specify a start address after the prompt:

\[
\text{(Start address (Wptr))}？
\]

Either press [RETURN] to accept the default address, or enter the desired address. The address can be entered as a decimal number, a hexadecimal number preceded by ‘\#’, or the short form ‘\%h...h’.

When a start address has been given, the following prompt is displayed:

\[
\text{Typed memory dump}
\]

0 - ASCII
1 - INT
2 - BYTE
3 - BOOL
4 - INT16
5 - INT32
6 - INT64 (Not implemented)
7 - REAL32 (Not implemented)
8 - REAL64 (Not implemented)
9 - CHAN

\[
\text{Which occam type ?}
\]

Give the number corresponding to the type you wish to display or press [RETURN] to accept the default type. Initially the default will be HEX; for subsequent use of the command the default takes the value of the last selected type.

ASCII arrays are displayed in the format used by the Monitor page command ‘ASCII’. Other types are displayed both in their normal representation and hexadecimal format.

The memory is displayed as thirteen rows of data. The address at the start of each line is an absolute address displayed as a hexadecimal number. The element specified by the start address is on the top row of the display.

Start addresses are aligned to the nearest valid boundary for the type, that is: BYTE and BOOL to the nearest byte; INT16 to the nearest even byte; INT, INT32 and CHAN to the nearest word.

\[ \text{Jump into program} \]

Same as [G] – starts or continues running the program.
L – Links

Displays information about simulated links.

The Links command displays the instruction pointer `Iptr`, workspace descriptor `Wdesc` and priority, of the processes waiting for communication on a link, or for a signal on the Event pin. If no process is waiting, the link is described as 'Empty'. Link connections on the processor, and the link from which the processor was booted are also displayed.

The format of the display is similar to the following:

```
Link 0 out Iptr: #80000256  Wdesc: #80000091 (Lo)
Link 1 out Empty
Link 2 out Empty
Link 3 out Empty
Link 0 in Empty
Link 1 in Empty
Link 2 in Empty
Link 3 in Empty

Link 0 connected to Host
Links 1, 2, 3 not connected

Booted from link 0
```

M – Memory map

This option is not applicable to the current version of isim, if used the following message will be displayed:

```
Memory Map Invalid
```

N – Create dump file

Creates a core dump file from which the program can be debugged off-line. The name of the file and the number of bytes to write must be specified. A file extension is not required and should not be specified. The dump file is automatically given the `.dmp` extension. This can be used by idebug, see chapter 4.

P – Program boot

Loads the program into transputer memory ('boots the program') so that debugging can start at beginning of the application program without stepping through bootstrap loading code. The program is loaded into memory but is not automatically run. This command can only be used prior to executing any other instructions.

Q – Quit

Quits the simulator, and returns to the host operating system.
280

14.4 Simulator commands

R – Run queues

This command displays Iptrs and Wdescs for processes waiting on the processor’s active process queues. If both high and low priority front process queues are empty, the following message is displayed:

Both process queues are empty

If neither queue is empty, you are required to specify the queue:

High or low priority process queue ? (H,L)

Type ‘H’ or ‘L’ as required. If only one queue is empty isim displays the non-empty queue.

The ▲, ▼, PAGE UP, and PAGE DOWN keys can be used to scroll the display.

S – Single step transputer instruction

This command executes the transputer instruction pointed to by Iptr. By repeating the command the user may single step through the program, observing the changes to the process queues and registers, as the display is updated.

T – Timer queue

This command displays Iptrs, Wdescs, and wake-up times for processes waiting on the processor’s timer queues. Prompts and displays are similar to those for the Run queue command.

U – Assign

Assigns a value to a register, Iptr or Wptr. To assign a value, specify the register by name (abbreviations are permitted), and give a value to be assigned to the register. This enables the program to be re-run (using G or J) with alternative values in the registers.

HELP

? – Help

Lists the available simulator commands.

REFRESH – Refresh

Refreshes the screen.
FINISH – Quit

Quits the simulator, and returns to the host operating system.

The ▲, ▼, PAGE UP, and PAGE DOWN keys can be used to scroll the display.

14.5 Batch mode operation

isim can be run in batch mode by setting up the environment variable ISIMBATCH. If this variable is defined on the system isim automatically selects batch mode operation.

14.5.1 Setting up ISIMBATCH

ISIMBATCH is set up on the system as an environment variable using the appropriate command for your host system.

VERIFY and NOVERIFY modes which enable and disable the output of input commands and user responses are defined by setting a value for ISIMBATCH. In MS-DOS the command to use is the set command. For example:

C:\ set ISIMBATCH=VERIFY
C:\ set ISIMBATCH=NOVERIFY

In UNIX the equivalent command is setenv and on VMS systems the command to use is define. Details of how to use these commands can be found in the user documentation for your system.

14.5.2 Input command files

In batch mode isim is driven from a command script containing simulator commands and responses to prompts. All prompts by isim must be followed by a valid response.

14.5.3 Output

Output can be written to a log file or displayed at the terminal. Input and output streams can be assigned to files or the user’s terminal by commands on the host.

isim can be set up to operate in VERIFY or NOVERIFY mode by setting a different values for ISIMBATCH. In VERIFY mode all prompts and user responses are included in the output.

14.5.4 Batch mode commands

Batch mode simulator commands ‘a’ through ‘u’ are the same as the interactive debugging commands. Two additional commands generate special batch mode output:
14.6 Error messages

<table>
<thead>
<tr>
<th>Key</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Query state</td>
<td>Displays values of registers and queue pointers.</td>
</tr>
<tr>
<td>.</td>
<td>Where</td>
<td>Displays next Iptr and transputer instruction.</td>
</tr>
</tbody>
</table>

**- Query state**

Displays information about the processor state, including current values of registers, queue pointers, and error flag status. For example:

```
Processor state
Iptr   #80000070
Wptr   #800000C8
Areg   #80000070
Breg   #800000C8
Creg   #80000010
Error  Clear
Halt on Error Set
Fptr1 (Low #00000000
Bptr1 queue) #00000000
Fptr0 (High #00000000
Bptr0 queue) #00000000
Tptr1 (timer #2D2D2D2D
Tptr0 (queues #2D2D2D2D
```

**- Where**

Displays the Iptr of the next instruction to execute and a disassembly of that instruction. For example:

```
Iptr #80000070. Low Priority, Next Instruction : ajw 42 - #2A
```

14.6 Error messages

**Cannot open bootfile 'filename'**

The file containing the code to be run could not be opened or could not be found.

**Environment variable 'IBOARDSIZE' does not exist**

Board memory size must be specified to the system using the the host environment variable IBOARDSIZE. Details of how to set up IBOARDSIZE on your system can be found in the Delivery Manual.

**Environment variable 'ITERM' not set up**

The ITERM definition file for the simulator function keys must be specified in the ITERM host environment variable.
IBOARDSIZE is too small (at least *number* bytes required)

The simulator requires a minimum memory size in order to run correctly. Modify IBOARDSIZE and retry the command.

*ITERM error*

Iterm initialisation has failed

The ITERM file for setting up the terminal codes is invalid. *ITERM error* describes the fault in the file.

Simulator terminated: Error flag set - *message*

Simulator messages may be output when the simulator halts (i.e. as an error condition). *message* can be one of:

- arithmetic overflow
- arithmetic underflow
- long overflow
- subscript out of range
- count out of range
- check single
- check word
- arithmetic exception
- floating point error

Simulator terminated: *message*

Simulator messages may be output when the simulator halts, due to an invalid operation within the program being simulated. *message* can be one of:

- attempt made to input from non-existent hard channel
  - Attempt to input from output link.
- attempt made to output to non-existent hard channel
  - Attempt to output to input link.
- attempt to output to unattached hard channel
  - Attempt to output on unattached link.
- attempt to read illegal memory byte at *address*
  - The memory address specified is invalid (not within IBOARDSIZE).
attempt to read illegal memory word at *address*

Invalid memory address or attempt to access non word aligned.

attempt to set illegal memory byte pointer

Invalid memory address (not within IBOARDSIZE).

attempt to set illegal memory word pointer

Invalid memory address or attempt to access non word aligned.

attempt to write illegal memory byte at *address*

Invalid memory address (not within IBOARDSIZE).

attempt to write illegal memory word at *address*

Invalid memory address or attempt to access non word aligned.

high priority process restored from save area

A swapped out low priority process has been written over during an interrupt.

illegal operand (*nnn*) to operate command

An attempt has been made to execute invalid instruction for the T425.

input from iserver when iserver outputting

ISERVER packet input before leading output sent.

inputting iserver packet larger than expected

Illegal ISERVER protocol packet on input.

output iserver packet larger than expected

Illegal ISERVER protocol packet on output.

output to iserver when iserver inputting

ISERVER packet output before response to last output received.
15 iSkip - Skip Loader

This chapter describes the skip loader tool that allows programs to be loaded onto transputer networks over the root transputer. The tool sets up a data transfer protocol on the root transputer that allows programs running on the rest of the network to communicate directly with the host.

15.1 Introduction

The skip tool iSkip prepares a network to load a program over the root transputer by setting up a transparent route-through process on the root transputer to transfer data from the application program running on the target network to and from the host computer. A subsequent call to iserver loads the program onto the network connected to the root transputer, but does not use the root transputer as part of the network. The root transputer is in effect rendered transparent to the rest of the network. The route-through process uses a simple protocol that transfers data byte by byte between the program and the host.

After iSkip has been invoked to set up the data link across the root transputer, the program can be loaded down the host link using iserver. iSkip can be used to skip any number of processors and load a program into any part of a network, see section 15.2.2.

iSkip itself may only be executed on 32 bit transputers which have more than 8 Kbytes of memory, although it may be used to reach both 16 and 32 bit transputers for target program execution.

15.1.1 Uses of the skip tool

The skip tool has two main uses:

1. To allow programs configured for specific arrangements of transputers to be loaded onto the target network without using the root transputer to run the program. The root transputer helps to load the program onto the network and subsequently provides a route-through process which transfers data from the application program to the host.

   Example of boards supplied by INMOS that can be used to skip load programs are the IMS B004 PC add-in board, which contains a single IMS T414 transputer, and the IMS B008 PC motherboard fitted with a TRAM in slot zero to act as the root transputer. Other slots on the motherboard can be used to accommodate the target network.

2. Programs configured for a network that normally incorporates the root transputer can be debugged without having to use idump to save root
transputer's memory to disk. Programs can be loaded into the network connected to the root transputer and the debugger can safely run on the root transputer without overwriting the program. The external network must have the correct number and arrangement of processors and memory for the program to be loaded.

This can make debugging transputer programs easier when an extra transputer is available.

15.2 Running the iskip loader

To invoke the iskip tool use the following command line:

```bash
iskip linknumber {options}
```

where: `linknumber` is the link on the root transputer to which the target transputer network is connected.

`options` is a list, in any order, of one or more options from Table 15.1.

Options must be preceded by '-' for UNIX-based toolsets and '/' for MS-DOS and VMS based toolsets.

Options may be given in any order.

Options may be entered in upper or lower case.

If no arguments are given on the command line a help page is displayed giving the command syntax.

<table>
<thead>
<tr>
<th>Option</th>

<td>Reset subsystem. Resets all transputers connected downstream of link <code>linknumber</code>. Does not reset the root transputer.</td>
</tr>
<tr>
<td>RP</td>
<td>A replacement for the <code>R</code> option when running programs on boards from certain vendors. Contact your supplier to see whether this option is applicable to your hardware. It does not apply to boards manufactured by INMOS.</td>
</tr>
</tbody>
</table>

Table 15.1 iskip options
15.2.1 Skipping a single transputer

This example illustrates how to use \texttt{iskip} to skip over the root transputer for the example network shown in Figure 15.1.

![Figure 15.1 Skipping a single transputer](image)

For further information about subsystem wiring see chapter 7 in the \textit{User Guide} and the debugger documentation in chapter 4 of this manual.

Subsystem wired down:

\begin{verbatim}
iskip 2 -r (UNIX based toolsets)
iskip 2 /r (MS-DOS/VMS based toolsets)
\end{verbatim}

In this example \texttt{iskip} is invoked for a network where the subsystem is wired \textit{down}. The network is prepared to load the program over the root transputer, which is connected to the network via link 2; the ‘r’ option resets the target network.

Subsystem wired subs:

\begin{verbatim}
iskip 2 -r -e (UNIX based toolsets)
iskip 2 /r /e (MS-DOS/VMS based toolsets)
\end{verbatim}

In this example \texttt{iskip} is invoked for a network where the subsystem is wired \textit{subs}. The ‘e’ option has been added to the example, to direct \texttt{iskip} to monitor the subsystem error status, see section 15.2.4.

15.2.2 Skipping multiple transputers

This example illustrates how to use \texttt{iskip} to skip over two transputers (starting with the root transputer) for the example network shown in Figure 15.2.

![Figure 15.2 Skipping over two transputers](image)
Normally `iskip` is invoked via its driver program; this resets the root transputer and loads the transputer bootable image `iskip.btl` onto the transputer (essentially it performs an `iserver -se -sb iskip.btl` operation). Note: because the root transputer is reset, running `iskip` twice in succession will not achieve any more than running `iskip` once; the second invocation will reset the first and load `iskip` onto the root transputer. In order to skip over more than one transputer, `iskip` must be loaded onto subsequent transputers by a 'different' method that does not involve resetting the root transputer. This is best illustrated by an example as shown below (for a network wired `subs`):

```
iskip 2 -r -e
iserver -se -ss -sc iskip.btl 0
```

```
iskip 2 /r /e
iserver /se /ss /sc iskip.btl 0
```

`iskip.btl` is the transputer bootable component of `iskip`, it may be found in the `tools` directory of this toolset release. For details of toolset directories see the delivery manual supplied with this toolset.

### 15.2.3 Loading a program

Once `iskip` has been invoked to prepare the network, the program is loaded by invoking `iserver` with the 'SE', 'SS' and 'SC' options. `iserver` must be invoked with the 'SE' option if the error flag is required to be monitored. This applies whether the `iskip` 'E' option is used or not. For example:

```
iserver -se -ss -sc myprog.btl 0
```

```
iserver /se /ss /sc myprog.btl
```

Note: After using the skip tool the root transputer must not be reset or analyzed, that is, `iserver` must not be invoked with the 'SR', 'SB', or 'SA' options, while `iskip` is required to run.

### 15.2.4 Monitoring the error status – option E

The `iskip` 'E' option should only be used when the sub-network is connected to the Subsystem port of the root transputer i.e. 'wired subs'. When the sub-network is connected to the Down port on the root transputer i.e. 'wired Down', the 'E' option must not be used.

The 'E' option instructs `iskip` to monitor the subsystem error status and terminate when it becomes set. When it terminates it sets its own error flag in order that the server may detect that an error in the subsystem has occurred. This allows the program to be debugged.

If the subsystem error status is not properly monitored when the program is run, the server may become suspended when a program error occurs. In these circumstances the server can be terminated using the host system BREAK key.
Note: There is a delay of one second after iskip is invoked with the 'E' option before monitoring of the subsystem error status begins; if the program fails before this the server may not terminate correctly and the host system BREAK key should be used.

15.2.5 Clearing the error flag

If either iskip or iserver detect that the error flag is set immediately a program starts executing it is likely that the network consists of more processors than are currently being used and that one or more of the unused processors has its error flag set.

On transputer boards the network may be reset using network check programs, such as ispy, which clear all error flags.

The ispy program is provided as part of the support software for some INMOS iq systems products. These products are available separately through your local INMOS distributor.

An alternative to using a network check program to clear the network is to load a dummy process onto each processor. In the act of loading the process code the error flag is cleared.

15.3 Error messages

This section lists error messages that can be generated by the skip tool.

Called incorrectly

Command line error. Check command line syntax and retry.

Cannot read server's command line

Syntax error. Retry the command.

Duplicate option: option

option was supplied more than once on the command line.

No filename supplied

No filename was supplied on the command line.

This option must be followed by a parameter: option

The option specified requires a parameter. Check syntax and retry.
15.3 Error messages

Unknown option: option

The specified option is invalid. Check option list and retry.

You must specify a link number (0 to 3)

A link number is required. Specify the number of the root transputer link to which the network is connected. If you specify the host link an error is reported.
Appendices
This appendix describes the standards and conventions used by INMOS toolsets for:

- Command line syntax
- Filenames
- Search paths
- File extensions
- Error message format

A.1 Command line syntax

All tools in the toolsets conform to a common command line format.

A.1.1 General conventions

- Commands, and their parameters and options, obey host system standards.
- Filenames, either directly specified on the command line or as arguments to options, must conform to the host system naming conventions.
- Options must be prefixed with the standard option prefix character for the operating system ('-' for UNIX based toolsets and '/' for VMS and MS-DOS based toolsets).
- Command line parameters and options can be specified in any order but must be separated by spaces.
- Lists of arguments to options, where allowed, must be enclosed in parentheses, and the items in the list must be separated by commas.
- If no parameters or options are specified the tool displays a help page that explains the command syntax.

A.1.2 Standard options

Standard command line options used in the toolsets have the same action for all tools. Standard options and their descriptions are given below.
A.2 Unsupported options

A number of tools have various command line options beginning with 'Z'. These options are used by INMOS for development purposes and have not been designed for users. As such they are unsupported and should not be used. INMOS cannot guarantee the results obtained from such options nor their continued presence in future toolset releases.

A.3 Filenames

File names generally follow the naming and character set conventions of the host operating system except that the following directory separator characters cannot be used within a filename:

- Colon ‘:’
- Semi–colon ‘;’
- Forward slash ‘/’
- Backslash ‘\’ (’¥’ for Japanese MS-DOS)
- Square brackets ‘[]’
- Round brackets ‘()’
- Angle brackets ‘<>’
- Exclamation mark ‘!’
- Equals sign ‘=’

A.4 Search paths

The tools locate files by searching a specified directory path on the host system. The path is specified using the host environment variable ISEARCH. The search rules for all tools are as follows:

1. If the filename contains a directory specification then the filename is used as given. Relative directory names are treated as relative to the directory in which the tool is invoked.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>Specifies an indirect file (command script).</td>
</tr>
<tr>
<td>I</td>
<td>Displays progress data in full.</td>
</tr>
<tr>
<td>O</td>
<td>Specifies an output file.</td>
</tr>
</tbody>
</table>
2 If no directory is specified the directory in which the tool is invoked is assumed.

3 If the file is not present in the current directory, the path specified by the environment variable (or logical name) ISEARCH is searched. If there are several files of the same name on this path, the first occurrence is used.

4 If the file is not found using the above rules, then the file is assumed to be absent, and an error is reported.

If no search path has been set up then only rules 1 and 2 apply.

By default all files are written to the current directory.

A.5 Standard file extensions

The INMOS toolsets use a standard set of file extensions for source and object files. In most cases these extensions must be specified on the command line for input files. They are automatically created for output files, unless an alternative file-name is specified on the command line.

A separate set of extensions for object files must be used where imakef is used to build programs for mixed processor networks. These are described separately in section A.6.
### A.5 Standard file extensions

#### A.5.1 Main source and object files

<table>
<thead>
<tr>
<th>Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>.btl</strong></td>
<td>Bootable file which can be loaded onto a transputer or transputer network. Created by <code>icollect</code> directly from a <code>.lk</code> file (single transputer programs) or from a <code>.cfb</code> file. Bootable files can be sent down a link by <code>iserver</code> for immediate execution. Contains information used by <code>iserver</code> to control the host link for execution. Also read by <code>idebug*</code>.</td>
</tr>
<tr>
<td><strong>.c</strong></td>
<td>C source files. Assumed by <code>icc</code>, the ANSI C compiler.</td>
</tr>
<tr>
<td><strong>.cfb</strong></td>
<td>Configuration binary file containing a description of how code is to be placed on a network, a description of the route to be used to load the network, and the parameters to be passed to each of the processes. Created by the configurer from a user-defined configuration description and read by <code>icollect</code> to prepare a bootable file and by <code>idebug*</code> to load a network for debugging.</td>
</tr>
<tr>
<td><strong>.cfs</strong></td>
<td>Configuration description file. This is a text file, created by the user and describes the hardware and software networks and the mapping between them. It also references the linked units and is used as input to the C configurer <code>iceonf</code>.</td>
</tr>
<tr>
<td><strong>.f77</strong></td>
<td>FORTRAN source files. Assumed by <code>if77</code>, the FORTRAN-77 compiler.</td>
</tr>
<tr>
<td><strong>.h</strong></td>
<td>Header files for use in C source code.</td>
</tr>
<tr>
<td><strong>.lk</strong></td>
<td>Linked unit. Created by <code>ilink</code> as an executable process with no external references. Used as input to <code>icollect</code> (single transputer programs) or within a configuration description. Also read by <code>idebug*</code>.</td>
</tr>
<tr>
<td><strong>.lib</strong></td>
<td>Library file containing a collection of binary modules. Created by <code>ilibr</code>.</td>
</tr>
<tr>
<td><strong>.occ</strong></td>
<td>occam source files. Assumed by <code>oc</code>, the occam 2 compiler.</td>
</tr>
<tr>
<td><strong>.pgm</strong></td>
<td>occam configuration description file. This is a text file, created by the user and describes the hardware and software networks and the mapping between them. It also references the linked units and is used as input to the occam configurer <code>occonf</code>.</td>
</tr>
<tr>
<td><strong>.teo</strong></td>
<td>Compiled binary module produced by all INMOS TCOFF compilers. Used as input to <code>ilink</code> and <code>ilibr</code>. Also read by <code>idebug*</code>.</td>
</tr>
</tbody>
</table>

* Not applicable to the FORTRAN toolset
A.5.2 Indirect input files (script files)

<table>
<thead>
<tr>
<th>Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.inc</td>
<td>Include files named in #INCLUDE compiler directives for OCCAM, or #include statements in configuration descriptions or in FORTRAN-77 statements.</td>
</tr>
<tr>
<td>.lbb</td>
<td>Library build files which specify the components of a library to lib.</td>
</tr>
<tr>
<td>.liu</td>
<td>Library usage files. Created and used by imakef.</td>
</tr>
<tr>
<td>.lnk</td>
<td>Linker indirect files which specify the components of a program to be linked. Also used by imakef when creating Makefiles.</td>
</tr>
</tbody>
</table>

A.5.3 Files read by the memory map tool imap

<table>
<thead>
<tr>
<th>Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.mxx</td>
<td>Map file output by the compiler. The characters 'xx' are determined by the 2nd and 3rd characters of the extension given to the compiler object file. For example if the compiler object file takes the default extension .tco, the information file is given the extension .mco.</td>
</tr>
<tr>
<td>.dxx</td>
<td>Map file output by the linker. The characters 'xx' are determined by the 2nd and 3rd characters of the extension given to the linker object file. For example if the linker object file takes the default extension .lku, the information file is given the extension .dku.</td>
</tr>
<tr>
<td>.map</td>
<td>Map file output by the collector.</td>
</tr>
</tbody>
</table>

*Note*: These extensions also satisfy imakef's requirements, see section A.6.

A.5.4 Other output files

<table>
<thead>
<tr>
<th>Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.bin</td>
<td>Binary format files produced by ieprom for loading into ROM.</td>
</tr>
<tr>
<td>.btr</td>
<td>Executable code without a bootstrap. Created by icollect and used as input to ieprom.</td>
</tr>
<tr>
<td>.clu</td>
<td>Configuration object file, created by the occam configurer occonf.</td>
</tr>
<tr>
<td>.hex</td>
<td>A hex dump of a file for loading onto a ROM by a custom ROM loader tool.</td>
</tr>
<tr>
<td>.ihx</td>
<td>Intel hex format files produced by ieprom for loading into ROM.</td>
</tr>
<tr>
<td>.mot</td>
<td>Motorola 'srecord' files produced by ieprom for loading into ROM.</td>
</tr>
<tr>
<td>.rsc</td>
<td>An .rsc file contains the code of a process together with a description of its requirements for data areas and parameters. It is created by the collector from a linked unit. The format is described in chapter 3. .rsc files are suitable for using with either the occam or C functions which support dynamic code loading.</td>

<tbody>
<tr>
<td>.dmp*</td>
<td>Memory dump and network dump files. Created by idump for debugging code on the root transputer (memory dump) or by idebug for off-line analysis of a program on a network (network dump). Read by the debugger for post-mortem debugging.</td>
</tr>
<tr>
<td>.itm</td>
<td>ITERM files containing information about the terminal. Used by tools such as idebug to handle the screen in a device-independent manner. Can also be created by users for other terminals. The file is referenced via the environment variable ITERM.</td>
</tr>
<tr>
<td>.mak</td>
<td>Makefile generated by imakef. This file may be input to a “make” utility to build the target file. May also be edited by the user.</td>
</tr>
</tbody>
</table>

* Not applicable to the FORTRAN toolset

A.6 Extensions required for imakef

The standard set of file extensions are adequate for simple programs executing on a single transputer, or on a network of transputers all of the same type. If the network is heterogeneous and a particular source file needs to be compiled for more than one transputer type, the following scheme can be used to identify the individual processor types and error modes.

If imakef is used to build the program, this scheme must be used.

The extended system uses extensions of the form .fpe:

where: f denotes the type of file and can take the following values:

- t for .tco equivalents.
- l for .lnk equivalents.
- c for .lkx equivalents.
- r for .rsc equivalents.

p denotes the transputer target type or class. This can take the following values:

2 - T212, T222, M212
3 - T225
4 - T414
5 - T425, T400, T426
8 - T800
9 - T801, T805
a - T400, T414, T425, T800, T801, T805
b - T400, T414, T425
e denotes the execution error mode. The values it can take are:

- h – on execution, an error will immediately halt the transputer.
- s – when an error occurs, this process will terminate.
- x – the program can be executed in either HALT or STOP mode.

A.7 Message handling

All tools in the toolsets display diagnostic messages in a standard format. This has certain advantages:

1. The tool generating the message can be identified even when the tool is run out of contact with the terminal.
2. User programs or system utilities can be used to detect and manipulate errors. Some host system editors permit automatic location of errors.

A.7.1 Message format

Diagnostic messages are displayed in a standard format by all tools. The generalized format can be expressed as follows:

```
```

where: severity indicates the severity level. Severity categories are described below.

toolname is the standard toolset name for the tool. Names used to rename tools by the user, are not used.

filename and linenumber indicate the file and line where an error occurred. They are only displayed if the error occurs in a file. They are commonly displayed when files of the wrong format are specified on the command line, for example, a source file is specified where an object file is expected.

message explains the error and may recommend an action.

A.7.2 Severities

The severity attached to the message indicates the importance of the diagnostic to the operation of the tool. It also implies a certain action taken by the tool.

Five severity categories are recognized:

*Information Warning Error Serious Fatal

Information messages provide the user with information about the functioning or performance of the tool. They do not indicate an error and no user action is required in response.
Warning messages identify minor logical inconsistencies in code, or warn of the impending generation of more serious errors. The tool continues to run and may produce usable output if no serious errors are encountered subsequently.

Error messages indicate errors from which the tool can recover in the short-term but may cause further errors to be generated which may lead to termination. The tool may continue to run but further errors are likely and the tool is likely to abort eventually. No output is produced.

Serious errors are errors from which no recovery is possible. Further processing is abandoned and the tool aborts immediately. No output is produced.

Fatal errors indicate internal inconsistencies in the software and cause immediate termination of the operation with no output. Fatal errors are unlikely to occur but if they do the fact should be reported to your local INMOS distributor or field applications engineer.

A.7.3 Runtime errors

Errors which prevent the program from being run are detected by the runtime system at startup or during program execution. These errors are displayed in a similar format to that used by the tools. All runtime errors are generated at Fatal severity and cause immediate termination of the program.
B Transputer types and classes

This appendix first identifies the INMOS transputer types supported by this toolset. It then explains the concept of transputer classes in terms of developing programs for multiple transputer targets. This includes compiling and linking program modules. The examples given are based on the 'Hello world' program, written in C and compiled with the ice compiler.

It also explains the command line options which can be used to specify a target processor or transputer class.

Note: the information given in this appendix covers the current range of INMOS transputers and language compilers; readers should ignore details of transputer types or languages which do not apply to this particular toolset.

B.1 Transputer types supported by this toolset

The ANSI C and occam 2 toolsets can be used to develop programs targetted at the following INMOS transputer types:

IMS M212, T212, T222, T225, T400, T414, T425, T426, T800, T801, T805.

The FORTRAN toolset can only be used to develop programs targetted at 32-bit transputers. This includes the following INMOS transputer types:

IMS T400, T414, T425, T426, T800, T801, T805.

The default type assumed by various tools, if none is specified on the command line, is T414.

B.2 Transputer types and classes

This section describes the meaning of transputer types and classes and how selection of the target processor affects the compilation and linking stages of program development. The section describes how to compile and link code targeted at a single processor type and then describes how to compile and link programs so that they can be executed on different processor types.

B.2.1 Single transputer type

For those who have a single transputer or indeed a network of transputers all of the same type, the compilation and linking stages of program development are very straightforward. Simply compile and link all your modules for the required processor.
Example: to compile and link for a T800:

```
  icc hello -t800
  ilink hello.tco -t800 -f cstartup.lnk (UNIX)
```

```
  icc hello /t800
  ilink hello.tco /t800 /f cstartup.lnk (MS-DOS and VMS)
```

For a T414 the command lines are simpler:

```
  icc hello
  ilink hello.tco -f cstartup.lnk (UNIX)
```

```
  icc hello
  ilink hello.tco /f cstartup.lnk (MS-DOS and VMS)
```

B.2.2 Creating a program which can run on a range of transputers

The compiler and linker use the concept of transputer class to enable programs to be developed which may be run on different transputer types without the need to recompile.

A transputer class identifies an instruction set which is common to all the processors in that class. When a program is compiled and linked for a transputer class it may be run on any member of that class.

Note: Code created for a transputer class will often be less efficient than code created for a specific processor type. Therefore, creating code for a transputer class is discouraged in situations where program efficiency is a primary concern; it should only be performed where there is a genuine need to produce code which will run on a range of transputers or to reduce the size of a support library, where program efficiency is not a major concern.

Table B.1 lists all the transputer classes which the compiler and linker support and indicates which processors the program can be run on.

<table>
<thead>
<tr>
<th>Transputer class</th>
<th>Processors which class can be run on</th>
</tr>
</thead>
<tbody>
<tr>
<td>T2 *</td>
<td>T212, M212, T222, T225</td>
</tr>
<tr>
<td>T3 *</td>
<td>T225</td>
</tr>
<tr>
<td>T4</td>
<td>T414, T400, T425, T426</td>
</tr>
<tr>
<td>T5</td>
<td>T400, T425, T426</td>
</tr>
<tr>
<td>T8</td>
<td>T800, T801, T805</td>
</tr>
<tr>
<td>T9</td>
<td>T801, T805</td>
</tr>
<tr>
<td>TA</td>
<td>T400, T414, T425, T426, T800, T801, T805</td>
</tr>
<tr>
<td>TB</td>
<td>T400, T414, T425, T426</td>
</tr>
<tr>
<td></td>
<td>* Not applicable to the FORTRAN toolset</td>
</tr>
</tbody>
</table>

Table B.1  Transputer classes and target processor
In order to develop a program which will run on different processor types, perform the following steps:

1. Identify the processors on which the program is to run.
2. Using Table B.1 select the class which may be run on all the target processors.
3. Compile and link all the program modules for this class.

For example, to create a program which will run on both a T400 and a T425, compile and link for transputer class T5:

```plaintext
  icc hello -t5
  ilink hello.tco -t5 -f cstartup.lnk  (UNIX)

  icc hello /t5
  ilink hello.tco /t5 /f cstartup.lnk  (MS-DOS and VMS)
```

Alternatively to create a program which will run on a T400, T425 or a T800, compile and link for transputer class TA:

```plaintext
  icc hello -ta
  ilink hello.tco -ta -f cstartup.lnk  (UNIX)

  icc hello /ta
  ilink hello.tco /ta /f cstartup.lnk  (MS-DOS and VMS)
```

Code compiled for a T414 (class T4) may be run on a T400 or T425, which form class T5.

Programs compiled for the T212, M212, or T222 transputers i.e. class T2, can be run on a T225 (class T3) because a T225 has a similar but larger instruction set than class T2 transputers. Similarly the T400, T425 and T426 have additional instructions to those of the T414. Likewise, code compiled for a T800 (class T8) may be run on a T801 or T805, which form class T9. Again the T801 and T805 have additional instructions to those of the T800. See section B.2.4.

B.2.3 Linked file containing code compiled for different targets

This section describes how object code compiled for one target processor or transputer class can be linked with code compiled for different transputer types or classes.

The ability to do this provides the user with greater flexibility in the use of program modules:

- An individual module can be compiled once e.g. for class T4, and then linked with separate programs to run on different processor types e.g. T414 and T425.
When the user is preparing a library for use by programs intended to run on different processor types, a single copy of code compiled for a transputer class can be inserted instead of multiple copies for specific transputers.

When linking a collection of compiled units together into a single linked unit, the user must select a specific transputer type or transputer class on which the linked unit is to run. As before, this determines the set of transputer types on which the code will run. When linking for a particular type or class, the linker will accept compilation units compiled for a compatible class. Table B.2 shows which transputer types and classes the linker will accept when linking for a particular class.

<table>
<thead>
<tr>

</tr>
<tr>
<td>TB</td>
<td>TB, TA</td>
</tr>
<tr>
<td>TA</td>
<td>TA</td>
</tr>
</tbody>
</table>

* Not applicable to the FORTRAN toolset

Table B.2  Linking transputer classes

For example, if the target processors are a T400 and a T425 the user may compile for classes T5 and TB and link the code for for class T5. Code for a different transputer class can be included in the final linked unit, as long as:

- It uses the instruction set or a subset, of the instruction set of the link class
- The calling conventions are the same.

Classes T8 and T9 cannot be linked with class TA. This is a change from early toolset releases e.g. the Dx11 C toolsets, the Dx05 occam toolsets and the Dx13 3L FORTRAN toolsets.

The reason why these classes cannot be linked together is explained in section B.2.4. which gives details of the differences between the instruction sets, as additional information.

A library can be made, consisting of the same modules compiled for different transputer types or classes. The user then needs only to specify the library file to the
linker, and the linker will choose a version of a required routine which is suitable for the system being linked.

The linker uses the rules given in Table B.2 to determine whether a compiled module, found in a library, is suitable for linking with the current system. So, for example, to create a library which may be linked with any transputer class or specific transputer type, all routines could be compiled for classes T2, TA and T8.

If there are a number of possible versions of a module in a library the best one (i.e. the most specific for the system being linked) is chosen.

**occam object files targetted at different targets**

For occam programs the above rules must also be applied during the program design stage when deciding which modules should call each other. Code for a different transputer class can be called provided that it uses the instruction set or a subset of the instruction set of the calling class. (This is because the compiler needs to know which modules to select from libraries containing copies for different processor types).

Table B.2 can be used as guide, by regarding the ‘link class’ as the ‘calling class’ and the ‘transputer classes which may be linked’, as the ‘transputer classes which may be called’.

**Note:** classes T8 and T9 cannot call class TA.

**Note:** At configuration level, code compiled for class TA can be run on a T8 transputer, provided it does not include any function which returns an arithmetic REAL. This is because of the different methods of evaluating REAL arithmetic for different transputer targets, see section B.2.4.

**B.2.4 Classes/instruction sets – additional information**

The instruction sets of the transputer classes differ in the following ways:

- Classes T2 and T3 support 16–bit transputers whereas all the other transputer classes support 32–bit transputers.

- Class T3 is the same as class T2 except that T3 has some extra instructions to perform CRC and bit operations, `dup`, double word indexing and includes special debugging functions.

- Class T5 is the same as class T4 except that T5 has extra instructions to perform CRC, 2D block moves, bit operations, double word indexing, special debugging functions and also includes the `dup` instruction.

- Class T9 is the same as class T8 except T9 has additional debugging instructions.

- The T800, T801 and T805 processors use an on-chip floating point processor to perform REAL arithmetic. Thus a large number of floating
point instructions are available for these transputers and for their associated classes T8 and T9. These instructions are listed in the instruction set appendix of the *User Guide*.

- For the T414, T400, T425 and T426 processors i.e. transputer classes T4 and T5 the implementation of REAL arithmetic is in software. These transputers make use of a small number of floating point support instructions. Details can be found in the instruction set appendix of the *User Guide*.

- The instruction set of class TA only uses instructions which are common to the T400, T414, T425, T426, T800, T801 and T805 transputers. Therefore it does not use the floating point instructions, the floating point support instructions or the extra instructions to perform CRC, 2D block moves or special debugging or bit operations and it does not use the *dup* instruction.

- The instruction set of class TB only uses instructions which are common to the T400, T414, T425 and T426 processors. Therefore it uses the floating point support instructions, but does not use the extra instructions to perform CRC, 2D block moves or special debugging or bit operations and it does not use the *dup* instruction.

When considering the similarities and differences in the instruction sets of different transputer classes it helps to divide them into the separate structures as shown in Figure B.1.

![Figure B.1 Structures for mixing transputer types and classes](image)

By comparison with Table B.2 it can be seen that a module may only be linked with modules compiled for a transputer class which belongs to the same structure.

Classes T2 and T3 are targeted at 16–bit transputers so it is obvious that they cannot be linked with the other classes which are all targeted at 32–bit transputers.
The reason why classes T8 and T9 cannot be linked with classes TA, TB, T5 or T4 is because floating point results from functions are returned in a floating point register for T8 and T9 code and in an integer register for all other 32-bit processors. Even if your code does not perform real arithmetic, linking code compiled for a T9 or T8 with code compiled for any of the other classes is not permitted.

To summarize, compiling code for the transputer classes TA and TB enables it to be run on a large number of transputer types, however, the code may not be as efficient as code compiled for one of the other transputer classes or for a specific transputer type. For example compiling code for class T5 enables the CRC and 2D block move instructions to be used, whereas these instructions are not available to code compiled for classes TA and TB.

B.3 Transputer type command line options

This section lists the command line options used to specify a target processor or transputer class. The options can be used with the following tools:

- `icc` - The ANSI C compiler.
- `oc` - The occam 2 compiler.
- `if77` - The FORTRAN–77 compiler.
- `ilink` - The toolset linker.
<table>

</tbody>
</table>

Table B.3  Transputer type command line options
This appendix provides a technical description of the host file server protocol for version 1.5 of the iserver. It also describes the basic set of server functions which all versions of iserver must support and includes a set of extensions which may be present in some versions of iserver.

C.1 iserver packets

Every communication, both to and from the server, is a packet comprising a counted array of bytes. The first two bytes are a (little endian) count of the following message length. This is followed by a tag byte which specifies the iserver command. The remaining bytes are parameters to the command. Results returned by the iserver have a result value in place of the tag byte.

```
| s1 | s2 | tag : parameters |
```

In occam this protocol is defined as:

```
INT16: []BYTE
```

In the to-server direction, there is a minimum packet length of 8 bytes (i.e. a minimum message length of 6 bytes). In both to and from directions there is a maximum packet length of 1040 bytes. The packet size must always be an even number of bytes. If the number of bytes is an odd a dummy byte must be added to the end of the packet and the packet byte count rounded up by one.

The server code on the host can take advantage of the fact that it will always be able to read 8 bytes from the link at the start of a transaction.

C.2 Server commands

The functions implemented by the server are separated into five groups:

- File commands
- Record Structured file commands
- Host commands
- Server commands
- Reserved and Third Party commands

72 TDS 367 01  March 1993
The following sections contain descriptions of each command under each of the five groups.

In the descriptions the arguments and results of server calls are listed in the order that they appear in the data part of the protocol packet. The length of a packet is the length of all the items concatenated together, rounded up to an even number of bytes.

**occam** types are used to define the format of data items in the packet. All integer types are communicated least significant byte first. Negative integers are represented in 2's complement. Strings and other variable length blocks are introduced by a 16 bit signed count.

All server calls return a result byte as the first item in the return packet. If the operation succeeds the result byte will be zero. If the operation fails the result byte will be non-zero. The result will be one (1) in the special case where the operation failed because it was not implemented. If the result is not zero, some or all of the return values may not be present, resulting in a smaller return packet than if the call was successful. All server calls will use, where possible, a failure code from Table C.1 to give details of the failure.¹

</tbody>
</table>

Table C.1  iserver failure codes

¹. Result values between 2 and 127 are defined to have particular meanings by **occam** server libraries, result values of 128 or above are specific to the implementation of a server.
C.3 File commands

Open files are identified with 32 bit descriptors. There are three predefined open files:

- 0 standard input
- 1 standard output
- 2 standard error

If one of these is closed it may not be reopened.

If an application is both reading and writing to a file, then no read operation can be followed directly with a write operation and vice versa. Fseek must be called between a read/write or write/read, otherwise the error code NoPosn will be returned.

When reading from a file open in text mode, the host's newline sequence will be translated into the single character \texttt{LINEFEED(0x0a)}. No translation will be performed on binary files.

When writing to a file open in text mode, the single character \texttt{LINEFEED (0x0a)} will be translated into the host's newline sequence. No translation will be performed on binary files.

C.3.1 Fopen – Open a file

Synopsis: \texttt{StreamId = Fopen (Name, Type, Mode )}

To server: \texttt{BYTE} \hspace{1cm} \texttt{Tag = 10}
\texttt{INT16::[]}\texttt{BYTE} \hspace{1cm} \texttt{Name}
\texttt{BYTE} \hspace{1cm} \texttt{Type = 1 or 2}
\texttt{BYTE} \hspace{1cm} \texttt{Mode = 1…6}

From server: \texttt{BYTE} \hspace{1cm} \texttt{Result}
\texttt{INT32} \hspace{1cm} \texttt{StreamId}

Fopen opens the file \texttt{Name and, if successful, returns a stream identifier \texttt{StreamId.}}

\texttt{Type can take one of two possible values:}

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Binary</td>
<td>The file will contain raw binary bytes.</td>
</tr>
<tr>
<td>2</td>
<td>Text</td>
<td>The file will be stored as text records. Text files are host-specified.</td>
</tr>
</tbody>
</table>
Mode can have 6 possible values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Input</td>
<td>Open an existing file for input</td>
</tr>
<tr>
<td>2</td>
<td>Output</td>
<td>Create a new file, or truncate an existing one, for output</td>
</tr>
<tr>
<td>3</td>
<td>Append</td>
<td>Create a new file, or append to an existing one, for output</td>
</tr>
<tr>
<td>4</td>
<td>ExistingUpdate</td>
<td>Open an existing file for update (both reading and writing), starting at the beginning of the file</td>
</tr>
<tr>
<td>5</td>
<td>NewUpdate</td>
<td>Create a new file, or truncate an existing one, for update</td>
</tr>
<tr>
<td>6</td>
<td>AppendUpdate</td>
<td>Create a new file, or append to an existing one, for update</td>
</tr>
</tbody>
</table>

When a file is opened for update (one of the last three modes above) then the resulting stream may be used for input or output. There are restrictions however; an output operation may not follow an input operation without an intervening Fseek, Ftell or Fflush operation.

The number of streams that may be open at one time is host-specified, but will not be less than eight (including the three predefines).

Return Codes

| Success | Failed | NoPriv | NoResource | NoFile |

C.3.2 Fclose – Close a file

Synopsis: Fclose( StreamId )

To server: BYTE
INT32

Tag = 11
StreamId

From server: BYTE

Result

Fclose closes a stream StreamId which should be open for input or output. Fclose flushes any unwritten data and discards any unread buffered input before closing the stream.

Return Codes

| Success | Failed | BadId | NoResource |

72 TDS 367 01 March 1993
C.3.3 Fread – Read a block of data

Synopsis: \[ \text{Data} = \text{Fread}( \text{StreamId, Count} ) \]

To server: 
- BYTE Tag = 12
- INT32 StreamId
- INT16 Count

From server: 
- BYTE Result
- INT16: \[ \text{[]BYTE} \] Data

This function should not be used. It has been included only for compatibility purposes. A replacement routine, FGetBlock, has been provided, which is described in C.3.5.

Fread reads Count bytes of binary data from the specified stream. Input stops when the specified number of bytes are read, or the end of file is reached, or an error occurs. If Count is less than one then no input is done. The stream is left positioned immediately after the data read. If an error occurs the stream position is undefined.

Result is always zero. The actual number of bytes returned may be less than requested and Feof and FerrStat should be used to check for status.

Return Codes
Success

C.3.4 Fwrite – Write a block of data

Synopsis: \[ \text{Written} = \text{Fwrite}( \text{StreamId, Data} ) \]

To server: 
- BYTE Tag = 13
- INT32 StreamId
- INT16: \[ \text{[]BYTE} \] Data

From server: 
- BYTE Result
- INT16 Written

This function should not be used. It has been included only for compatibility purposes. A replacement routine, FPutBlock, has been provided, which is described in C.3.6.

Fwrite writes a given number of bytes of binary data to the specified stream, which should be open for output. If the length of Data is less than zero then no output is done. The position of the stream is advanced by the number of bytes actually written. If an error occurs then the resulting position is undefined.
Fwrite returns the number of bytes actually output in Written. Result is always zero. The actual number of bytes returned may be less than requested and Feof and FerrStat should be used to check for status.

If the StreamId is 1 (standard output) then the write is automatically flushed.

Return Codes

Success

C.3.5 FGetBlock – Read a block of data and return success

Synopsis: Data = FGetBlock( StreamId, Count )

To server: BYTE Tag = 23
INT32 StreamId
INT16 Count

From server: BYTE Result
INT16: : []BYTE Data

FGetBlock reads Count bytes of binary data from the specified stream. Input stops when the specified number of bytes are read, or the end of file is reached, or an error occurs. If Count is less than one then no input is done. The stream is left positioned immediately after the data read. If an error occurs the stream position is undefined.

The actual number of bytes returned may be less than requested. This is considered a failure. Result will contain 0 to indicate success, anything else failure, in which case Feof and FerrStat should be used to check for status.

This function is preferred over the Fread function which should no longer be used.

Return Codes

Success Failed Truncated BadId
C.3.6  **FPutBlock** – Write a block of data and return success

**Synopsis:**  
Written = FPutBlock( StreamId, Data )

**To server:**  
BYTE Tag = 24  
INT32 StreamId  
INT16: : [] BYTE Data

**From server:**  
BYTE Result  
INT16 Written

**FPutBlock** writes a given number of bytes of binary data to the specified stream, which should be open for output. If the length of Data is less than or equal to zero then no output is done. The position of the stream is advanced by the number of bytes actually written. If an error occurs then the resulting position is undefined.

**FPutBlock** returns the number of bytes actually output in Written. The actual number of bytes returned may be less than requested. Result will contain 0 to indicate success, anything else failure, in which case Feof and FerrStat should be used to check for status.

If the **StreamId** is 1 (standard output) then the write is automatically flushed.

This function is preferred over the **Fwrite** function which should no longer be used.

**Return Codes**

Success   Failed   NoResource   BadId   NoPosn

C.3.7  **Fgets** – Read a line

**Synopsis:**  
Data = Fgets( StreamId, Count )

**To server:**  
BYTE Tag = 14  
INT32 StreamId  
INT16 Count

**From server:**  
BYTE Result  
INT16: : [] BYTE Data

**Fgets** reads a line from a stream which must be open for input. Characters are read until end of file is reached, a newline is seen or the number of characters read is equal to **Count**.

If the input is terminated because a newline is seen then the newline sequence is **not** included in the returned array.
If end of file is encountered and nothing has been read from the stream then `Fgets` fails.

**Return Codes**

| Success | Failed | BadId | NoPosn |

**C.3.8 Fputs – Write a line**

**Synopsis:** `Fputs( StreamId, String )`

**To server:**
- BYTE \quad Tag = 15
- INT32 \quad StreamId
- INT16::[]BYTE \quad String

**From server:**
- BYTE \quad Result

`Fputs` writes a line of text to a stream which must be open for output. The host-specified convention for newline will be appended to the line and output to the file. The maximum line length is host-specified.

**Return Codes**

| Success | Failed | NoResource | BadId | NoPosn |

**C.3.9 Fflush – Flush a stream**

**Synopsis:** `Fflush( StreamId )`

**To server:**
- BYTE \quad Tag = 16
- INT32 \quad StreamId

**From server:**
- BYTE \quad Result

`Fflush` flushes the specified stream, which should be open for output. Any internally buffered data is written to the destination device. The stream remains open.

**Return Codes**

| Success | Failed | NoResource | BadId |
C.4 Record Structured file commands

This section describes the commands for record structured files. File formats are discussed in Section C.8.

C.4.1 FopenRec – Open a record structured file

Synopsis: StreamId, RealMrs = FopenRec( Name, Type, Mode, Mrs )

To server: BYTE Tag = 26
INT16 : [] BYTE Name
BYTE Organisation = 3 ... 4
BYTE Mode = 1 ... 6
BYTE Type = 0 ... 2
BYTE Format = 0 ... 1
INT32 Mrs

From server: BYTE Result
INT32 RealMrs
INT32 StreamId
BYTE RealType

FopenRec opens the file Name and, if successful, returns a stream identifier StreamId.

Organisation can take one of two possible values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Variable</td>
<td>The file will be organized in records of variable length. The maximum record size is contained in the Mrs field.</td>
</tr>
<tr>
<td>4</td>
<td>Fixed</td>
<td>The file will be organized in records of fixed length. The size of a record is supplied in the Mrs field. Record files are implemented in a host-specific way.</td>
</tr>
</tbody>
</table>

For each organization, Type can have one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Don'tCare</td>
<td>Use whatever type is most natural, and return the type in RealType.</td>
</tr>
<tr>
<td>1</td>
<td>Stream</td>
<td>Use streams.</td>
</tr>
<tr>
<td>2</td>
<td>Record</td>
<td>Use record oriented files.</td>
</tr>
</tbody>
</table>
Format can take one of two possible values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Formatted</td>
<td>Formatted record structured file</td>
</tr>
<tr>
<td>1</td>
<td>Unformatted</td>
<td>Unformatted record structured file</td>
</tr>
</tbody>
</table>

Mode can have 6 possible values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Input</td>
<td>Open an existing file for input</td>
</tr>
<tr>
<td>2</td>
<td>Output</td>
<td>Create a new file, or truncate an existing one, for output</td>
</tr>
<tr>
<td>3</td>
<td>Append</td>
<td>Create a new file, or append to an existing one, for output</td>
</tr>
<tr>
<td>4</td>
<td>ExistingUpdate</td>
<td>Open an existing file for update (both reading and writing), starting at the beginning of the file</td>
</tr>
<tr>
<td>5</td>
<td>NewUpdate</td>
<td>Create a new file, or truncate an existing one, for update</td>
</tr>
<tr>
<td>6</td>
<td>AppendUpdate</td>
<td>Create a new file, or append to an existing one, for update</td>
</tr>
</tbody>
</table>

When a file is opened for update (one of the last three modes above) then the resulting stream may be used for input or output. There are restrictions however; an output operation may not follow an input operation without an intervening `Fseek`, `Ftell` or `Fflush` operation.

When an existing file is opened, the record size supplied in the open request is compared with that stored in the file if possible (some hosts do not record this information). If they are different then the open fails. If the real record size is not available, it is considered to be the same as the requested record size, and so the open can succeed. The actual record size for the file is returned in `RealMrs`.

The number of streams that may be open at one time is host-specified, but will not be less than eight (including the three predefineds).

Return Codes

Success Failed NoPriv NoResource NoFile
NotAvailable
C.4.2 FGetRec – Read a record

Synopsis:  \[ \text{Data} = \text{FGetRec} ( \text{StreamId} ) \]

To server:  
\begin{align*} 
\text{BYTE} & \quad \text{Tag} = 27 \\
\text{INT32} & \quad \text{StreamId} \\
\text{INT16} & \quad \text{ChunkSize} \\
\text{INT32} & \quad \text{Offset} \\
\text{BYTE} & \quad \text{PerformRead} 
\end{align*}

From server:  
\begin{align*} 
\text{BYTE} & \quad \text{Result} \\
\text{INT32} & \quad \text{RecordSize} \\
\text{INT16::[BY} & \quad \text{Data} 
\end{align*}

FGetRec reads a record from a record stream which must be open for input.

If an end of file record is encountered then FGetRec fails. If PerformRead is non-zero, then a record is transferred from the file specified by StreamId into the server's buffer, otherwise, data from the previous FGetRec is transferred. If PerformRead is zero, and no records have ever been read from StreamId, then FGetRec fails. ChunkSize specifies the number of bytes to be transferred, starting at byte number Offset from the record buffer.

Return Codes

Success   Failed   BadId   NoPosn   EOF

C.4.3 FPutRec – Write a record

Synopsis:  \[ \text{FPutRec} ( \text{StreamId}, \text{Record} ) \]

To server:  
\begin{align*} 
\text{BYTE} & \quad \text{Tag} = 28 \\
\text{INT32} & \quad \text{StreamId} \\
\text{INT32} & \quad \text{RecordSize} \\
\text{INT16} & \quad \text{ChunkSize} \\
\text{INT32} & \quad \text{Offset} \\
\text{BYTE} & \quad \text{PerformWrite} \\
\text{INT16::[BY} & \quad \text{Record} 
\end{align*}

From server:  
\begin{align*} 
\text{BYTE} & \quad \text{Result} 
\end{align*}

FPutRec writes a record to a record stream which must be open for output. ChunkSize specifies the number of bytes to be transferred, starting at byte number Offset into the record buffer. RecordSize specifies the size of the entire record. If PerformWrite is non-zero, then a record is transferred to the file specified by StreamId from the server's buffer, otherwise, data from a previous record is transferred.
Return Codes
Success  Failed  BadId  NoPosn

C.4.4 FputEOF – Write an end of file record

Synopsis:  FputEOF( StreamId )

To server:  BYTE  Tag = 29
             INT32  StreamId

From server:  BYTE  Result

FPutEOF writes an end of file record to a record structured file. When the file is closed, the file will be truncated after the first end-of-file record and data after it will be lost.

Return Codes
Success  Failed  BadId

C.4.5 Fseek – Set position in a file

Synopsis:  Fseek( StreamId, Offset, Origin )

To server:  BYTE  Tag = 17
             INT32  StreamId
             INT32  Offset
             INT32  Origin

From server:  BYTE  Result

Fseek sets the file position for the specified stream. A subsequent read or write will access data at the new position.

For a binary file the new position will be Offset characters from Origin which may take one of three values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set</td>
<td>The beginning of the file.</td>
</tr>
<tr>
<td>2</td>
<td>Current</td>
<td>The current position in the file.</td>
</tr>
<tr>
<td>3</td>
<td>End</td>
<td>The end of the file.</td>
</tr>
</tbody>
</table>

For a text stream, Offset must be zero or a value returned by Ftell. If the latter is used then Origin must be set to 1. For a record structured file Offset is the number of records to seek from Origin.
Return Codes
Success   Failed   BadId

C.4.6  Ftell – Find out position in a file

Synopsis:   Position = Ftell( StreamId )

To server:   BYTE   Tag = 18
              INT32   StreamId

From server:   BYTE   Result
               INT32   Position

Ftell returns the current file position for StreamId. For record structured files, the Position is the record number relative to the start of the file.

Return Codes
Success   Failed   BadId

C.4.7  Feof – Test for end of file

Synopsis:   Feof( StreamId )

To server:   BYTE   Tag = 19
              INT32   StreamId

From server:   BYTE   Result

Feof succeeds if the end of file indicator for StreamId is set. Note that the definition of ‘end of file’ is any attempt to read past the last byte in the file. i.e. Reading the last byte in a file will not set EOF; attempting to read the next byte will.

Return Codes
Success   Failed   BadId
C.4.8 Ferror – Get file error status

Synopsis: \[ \text{ErrorNo, Message} = \text{Ferror(StreamId)} \]

To server: \[
\begin{align*}
\text{BYTE} & \quad \text{Tag} = 20 \\
\text{INT32} & \quad \text{StreamId}
\end{align*}
\]

From server: \[
\begin{align*}
\text{BYTE} & \quad \text{Result} \\
\text{INT32} & \quad \text{ErrorNo} \\
\text{INT16::[]BYTE} & \quad \text{Message}
\end{align*}
\]

This function should not be used. It has been included only for compatibility purposes. A replacement routine, FGetBlock, has been provided, which is described in C.3.5.

Ferror succeeds if the error indicator for StreamId is set. If it is, Ferror returns a host-defined error number and a (possibly null) message corresponding to the last file error on the specified stream. The maximum size of Message will be restricted to 506 bytes for compatibility purposes. If the message is longer, then it will be truncated to fit and Ferror will fail.

Return Codes

Success    Failed

C.4.9 Remove – Delete a file

Synopsis: \[ \text{Remove( Name )} \]

To server: \[
\begin{align*}
\text{BYTE} & \quad \text{Tag} = 21 \\
\text{INT16::[]BYTE} & \quad \text{Name}
\end{align*}
\]

From server: \[ \text{BYTE} \quad \text{Result} \]

Remove deletes the named file.

Return Codes

Success    Failed    NoPriv    NoFile
C.4.10 Rename – Rename a file

Synopsis: Rename( OldName, NewName )

To server: BYTE Tag = 22
          INT16:[]BYTE OldName
          INT16:[]BYTE NewName

From server: BYTE Result

Rename changes the name of an existing file OldName to NewName.

Return Codes
Success Failed NoPriv NoFile

C.4.11 Isatty – Discover if a stream is connected to a terminal

Synopsis: Isatty( StreamId )

To server: BYTE Tag = 25
          INT32 StreamId

From server: BYTE Result
             BYTE Istty

Isatty determines if the stream specified by StreamId is connected to a terminal. Any non-zero value in Isatty indicates that the stream is connected to a terminal.

Return Codes
Success Failed BadId
C.4.12 FileExists – Check to see if a file exists

Synopsis: \( \text{Exists} := \text{FileExists}(\text{Name}) \)

To server: 
- BYTE Tag = 80
- INT16::[]BYTE Name

From server: 
- BYTE Result
- BYTE Exists

FileExists checks to see if the file \text{Name} exists. Any non-zero value in \text{Exists} indicates that the file does exist.

Return Codes
Effect: Success Failed

C.4.13 FerrStat – Get file error status

Synopsis: \( \text{ErrorNo, Message} = \text{FerrStat}(\text{StreamId}) \)

To server:
- BYTE Tag = 82
- INT32 StreamId
- INT16 MessLen

From server:
- BYTE Result
- INT32 ErrorNo
- INT16::[]BYTE Message

FerrStat succeeds if the error indicator for \text{StreamId} is set. If it is, FerrStat returns a host-defined error number and a (possibly null) message corresponding to the last file error on the specified stream. The maximum size of Message is restricted to MessLen bytes. If the message is longer, then it will be truncated to fit and FerrStat will fail with status of Truncated.

Return Codes
Effect: Success Failed Truncated
C.5  Host commands

C.5.1  Getkey – Get a keystroke

Synopsis: Key = GetKey()

To server: BYTE  Tag = 30

From server: BYTE  Result
                BYTE  Key

GetKey gets a single character from the keyboard. The keystroke is waited on indefinitely and will not be echoed. The effect on any buffered data in the standard input stream is host-defined. It should be noted that GetKey will only get one character from the keyboard stream; if a single key-press results in more than one character being generated, then GetKey/Pollkey should be called as many times as required to read them all.

Return Codes

Success  Failed

C.5.2  Pollkey – Test for a key

Synopsis: Key = PollKey()

To server: BYTE  Tag = 31

From server: BYTE  Result
                BYTE  Key

PollKey gets a single character from the keyboard. If a keystroke is not available then PollKey returns immediately with a non-zero result. If a keystroke is available it will not be echoed. The effect on any buffered data in the standard input stream is host-defined. It should be noted that PollKey will only get one character from the keyboard stream; if a single key-press results in more than one character being generated, then GetKey/Pollkey should be called as many times as required to read them all.

Return Codes

Success  Failed
C.5.3 RequestKey – Request a single keyboard ‘event’

Synopsis: \[ \text{Result} = \text{RequestKey()} \]

To server: \( \text{BYTE} \quad \text{Tag} = 36 \)

From server: \( \text{BYTE} \quad \text{Result} \)

This command should never be generated by an application. It may be used by the \textit{linkops} server to improve performance over a network.

Once \textit{iserver} has received one of these requests, it monitors the keyboard and if a key is pressed, it generates a keyboard ‘event’ across the link. This event will never reach the application since it will have been filtered out by the \textit{linkops} server. Each \textit{RequestKey} command will only solicit one keyboard event. The ‘event’ that \textit{iserver} generates looks exactly like the reply to the \textit{GetKey} command. It will only be generated while \textit{iserver} is idle (waiting for another \textit{iserver} request to arrive).

Return Codes

Success & Failed

C.5.4 Getenv – Get environment variable

Synopsis: \[ \text{Value} = \text{Getenv( Name )} \]

To server: \( \text{BYTE} \quad \text{Tag} = 32 \)
(\( \text{INT16::[]} \quad \text{BYTE} \quad \text{Name} \))

From server: \( \text{BYTE} \quad \text{Result} \)
(\( \text{INT16::[]} \quad \text{BYTE} \quad \text{Value} \))

This function should not be used. It has been included only for compatibility purposes. A replacement routine, \textit{Translate}, has been provided, which is described in C.5.7.

\textit{Getenv} returns a host-defined environment string for \textit{Name}. If \textit{Name} is undefined then \text{Result} will be non-zero. If the resultant environment string for \textit{Name} is longer than 509 bytes, then it will be truncated to fit and \textit{Getenv} will fail.

Return Codes

Success Failed

72 TDS 367 01 March 1993
C.5.5 Time – Get the time of day

Synopsis: \( \text{LocalTime}, \text{UTCTime} = \text{Time()} \)

To server: BYTE Tag = 33

From server: BYTE Result
UNSIGNED INT32 LocalTime
UNSIGNED INT32 UTCTime

Time returns the local time and \textit{Coordinated Universal Time} if it is available. Both times are expressed as the number of seconds that have elapsed since midnight on 1st January, 1970. If UTC time is unavailable then it will have a value of zero.

Return Codes
Success Failed

C.5.6 System – Run a command

Synopsis: \( \text{Status} = \text{System( Command )} \)

To server: BYTE Tag = 34
INT16::[]BYTE Command

From server: BYTE Result
INT32 Status

System provides access to the host's command processor, if one is available. If the length of \text{Command} is zero, then the command processor will not be invoked (and the empty string therefore not executed), and \text{System} will succeed only if a command processor is available. The value of \text{Status} is undefined in this case. If the length of \text{Command} is non-zero, then the string is passed to the command processor, which will attempt to execute it. In this case \text{Status} is the return value of the command, which is host-defined.

Return Codes
Success Failed NoResource
C.5.7 Translate – Translate an environment variable

Synopsis: \[ \text{Value} = \text{Translate}(\text{Name}, \text{Length}) \]

To server:  
- \text{BYTE} \quad \text{Tag} = 81
- \text{INT32} \quad \text{Offset}
- \text{INT16} \quad \text{Length}
- \text{INT16:[]}\text{BYTE} \quad \text{Name}

From server:  
- \text{BYTE} \quad \text{Result}
- \text{INT32} \quad \text{TotalLength}
- \text{INT16:[]}\text{BYTE} \quad \text{Value}

\text{Translate} returns a host-defined environment string for \text{Name}. If \text{Name} is undefined then Result will be non-zero. Data is transferred from the resultant string starting at \text{Offset} for \text{Length} bytes. If \text{Offset} is beyond the end of the string, then an empty (zero length) string will be returned. The \text{TotalLength} field of the reply contains the total length of the translated string.

Return Codes

Success Failed
C.6 Server commands

C.6.1 Exit – Terminate the server

Synopsis: Exit( Status )

To server: BYTE Tag = 35
INT32 Status

From server: BYTE Result

Exit terminates the server, which exits returning Status to its caller.

If Status has the special value 999999999 then the server will terminate with a host-specific 'success' result.

If Status has the special value -999999999 then the server will terminate with a host-specific 'failure' result.

Return Codes

Success

C.6.2 CommandLine – Retrieve the server command line

Synopsis: String = CommandLine( All )

To server: BYTE Tag = 40
BYTE All

From server: BYTE Result
INT16::[]BYTE String

This function should not be used. It has been included only for compatibility purposes. A replacement routine, CommandArgs, has been provided, which is described in C.6.6.

CommandLine obtains the command line passed to the server. The server is passed the command line arguments as a number of discrete items. The items are built into a command string using the following rules.

- The individual items are concatenated together into a string, with a single space (0x20) being inserted between each item.
- Any quote character (0x22) found in any item is quoted. e.g. " becomes "".
- Any command line item found to contain whitespace (0x20 or 0x09) has a quote character prefixed to it and another added after it.
CommandLine returns the command line passed to the server on invocation. On certain operating systems it is possible to quote arguments on the command line. The quotes themselves have been removed by the time iserver gets to see the arguments. When building the command line to pass on to the application, iserver places quotes (0x22) around any argument containing whitespace. Any genuine quote characters in the command line are quoted. e.g. " becomes "".

If All is zero the returned string is the command line, with the server name, arguments that the server recognized (including any parameters to the arguments) removed.

If All is non-zero then the string returned is the entire command vector as passed to the server on startup, including the name of the server command itself.

Return Codes
Success Failed

C.6.3 Core – Read peeked memory

Synopsis Data = Core( Offset, Length )

To server: BYTE Tag = 41
INT32 Offset
INT16 Length

From server: BYTE Result
INT16::[]BYTE Core

Core returns the contents of the root transputer’s memory, as peeked from the transputer when the server was invoked with the analyze option.

Core fails if Offset is larger than the amount of memory peeked from the transputer or if the transputer was not analyzed.

If (Offset + Length) is larger than the total amount of memory that was peeked then as many bytes as are available from the given offset are returned.

If Offset and Length are both zero, the the result of this function will indicate if the transputer was analyzed and peeked by the server.

Return Codes
Success Failed

72 TDS 367 01 March 1993
C.6.4  Version – Find out about the server

Synopsis:  Id = Version()

To server:  BYTE  Tag = 42

From server:  BYTE  Result
      BYTE  Version
      BYTE  Host
      BYTE  OS
      BYTE  Board

Use of this function is discouraged. To obtain similar information in a more portable
manner, use the function GetInfo (C.6.5).

Version returns four bytes containing identification information about the server
and the host it is running on.

If any of the bytes has the value 0 then that information is not available.

Version identifies the server version. The byte value should be divided by ten to
yield a version number

Host identifies the host box. Currently 8 are defined:

<table>
<thead>
<tr>
<th>Value</th>
<th>Host</th>
<th>Value</th>
<th>Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PC</td>
<td>2</td>
<td>NEC-PC</td>
</tr>
<tr>
<td>3</td>
<td>VAX</td>
<td>4</td>
<td>Sun 3</td>
</tr>
<tr>
<td>5</td>
<td>IBM 370</td>
<td>6</td>
<td>Sun 4</td>
</tr>
<tr>
<td>7</td>
<td>Sun 386i</td>
<td>8</td>
<td>Apollo</td>
</tr>
<tr>
<td>9</td>
<td>Atari</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

OS identifies the host environment. Currently 5 are defined:

<table>
<thead>
<tr>
<th>Value</th>
<th>Operating system</th>
<th>Value</th>
<th>Operating system</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>DOS</td>
<td>2</td>
<td>Helios</td>
</tr>
<tr>
<td>3</td>
<td>VMS</td>
<td>4</td>
<td>SunOS</td>
</tr>
<tr>
<td>5</td>
<td>CMS</td>
<td>6</td>
<td>TOS</td>
</tr>
</tbody>
</table>

March 1993
Board identifies the interface board. Currently 12 are defined:

<table>
<thead>
<tr>
<th>Value</th>
<th>Board</th>
<th>Value</th>
<th>Board</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>IMS B004</td>
<td>2</td>
<td>IMS B008</td>
</tr>
<tr>
<td>3</td>
<td>IMS B010</td>
<td>4</td>
<td>IMS B011</td>
</tr>
<tr>
<td>5</td>
<td>IMS B014</td>
<td>6</td>
<td>DRX-11</td>
</tr>
<tr>
<td>7</td>
<td>Caplin QT0</td>
<td>8</td>
<td>IMS B015</td>
</tr>
<tr>
<td>9</td>
<td>IBM CAT</td>
<td>10</td>
<td>IMS B016</td>
</tr>
<tr>
<td>11</td>
<td>UDP</td>
<td>12</td>
<td>TCPlink</td>
</tr>
<tr>
<td>13</td>
<td>ACSILA</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

INMOS reserves numbers up to and including 127 for these three fields.

Return Codes

Success Failed

C.6.5 GetInfo – Obtain information about the host and server

Synopsis: \( \text{NoOfBytes} = \text{GetInfo( Item, Buffer )} \)

To server: \( \text{BYTE} \) \( \text{BYTE} \) \( \text{INT16} \) \( \text{Tag} = 43 \) \( \text{Item} \) \( \text{ReplySize} \)

From server: \( \text{BYTE} \) \( \text{Result} \)

GetInfo is used to obtain host and server specific information in as portable a fashion as possible. \( \text{ReplySize} \) specifies the maximum size of the reply in bytes. If the reply exceeds this value, it will be truncated and an appropriate failure status will be returned. Values for \( \text{Item} \) and their representation are shown in Table C.2.

<table>
<thead>
<tr>

</tbody>
</table>

Table C.2 Results of GetInfo command
A BOOL will be represented as a single byte, with any non-zero value meaning TRUE, and zero FALSE.

Return Codes

Success  Failure  NoPriv  Truncated

C.6.6 CommandArgs – Retrieve the server command line arguments

Synopsis: \( \text{String} = \text{CommandArgs}( \text{Argno}, \text{Length} ) \)

To server: \( \text{BYTE} \) \( \text{INT16} \) \( \text{INT16} \) \( \text{Tag} = 83 \) \( \text{Argno} \) \( \text{Length} \)

From server: \( \text{BYTE} \) \( \text{INT16} \) \( \text{BYTE} \) \( \text{INT16} \) \( \text{[]BYTE} \) \( \text{Result} \) \( \text{NumArgs} \) \( \text{ServerArg} \) \( \text{String} \)

CommandArgs provides access to the server’s command line. \( \text{Argno} \) specifies the command line argument number and is used as an index into the server’s \( \text{argv} \) array. \( \text{Length} \) specifies the maximum length of \( \text{String} \). If \( \text{String} \) is too big, it will be truncated to fit, and a status of Truncated will be returned. If \( \text{ServerArg} \) is non-zero, it indicates that \( \text{String} \) was recognized as a server argument, and should be ignored by the application. \( \text{NumArgs} \) is the highest argument number which may be requested, and is the equivalent of the C variable \( \text{argc} \). Argument number zero is always present.

Return Codes

Success  Failed  Truncated
C.7 Reserved Tags and Third Party Tags

The following tags have been reserved for specific applications or by Third Parties for use in their own servers. Their use is not encouraged, since the third party tags will not be present in the standard INMOS server.

C.7.1 MSDOS – Perform MS-DOS specific function

Synopsis: MsDos(Command)

To server: BYTE Tag = 50
           BYTE Function code
           Function specific data

From server: BYTE Result
              Function specific results.

MSDOS is used to perform a number of MS-DOS specific functions. This is used to support some early INMOS PC-based programs. Use of this function is discouraged for portability reasons. The functions supported are shown in Table C.3.

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<td>Write to a port.</td>
</tr>
<tr>
<td>5</td>
<td>PortRead</td>
<td>Read from a port.</td>
</tr>
</tbody>
</table>

Table C.3 MS-DOS functions

Return Codes
Success    Failed
C.7.2 SocketA – make a socket library call

Synopsis: BYTE Tag = 70
BYTE Socket operation
Function specific data.

From server: BYTE Result
Function specific results.

This function allows an application to make a socket library call.

Return Codes
Success   Failed

C.7.3 SocketM – make a socket library call

Synopsis: BYTE Tag = 71
BYTE Socket operation
Function specific data.

From server: BYTE Result
Function specific results.

This function allows an application to make a socket library call.

Return Codes
Success   Failed

C.7.4 ALSYS – Perform Alsys specific function

Synopsis: Alsys(...)

To server: BYTE Tag = 100
Function specific data

From server: BYTE Result
Function specific results

Alsyst is used to perform a number of Alsys specific functions. This is used to support the Alsyst compilers.
C.7.5 KPAR – Perform Kpar specific function

Synopsis: Kpar(...)

To server: BYTE Tag = 101
Function specific data

From server: BYTE Result
Function specific results

This is used to perform a number of Kpar specific functions. This is used to support Kpar tools.

C.8 Record Structured file format

Under VAX/VMS, record structured files are implemented using the VAX Record Management Service (VAX/RMS). Under all other hosts record structured files are implemented using binary files. Files created are of a similar format to that used by Sun FORTRAN.

C.8.1 SunOS and MS–DOS

Formatted Sequential

Each record in a Formatted Sequential file has a linefeed character (0x0a) appended to it. Thus an extra byte per record is required. i.e.

```
record data linefeed
```

Unformatted Sequential

Unformatted Sequential files are implemented by prefixing and suffixing each record with a four byte length field, most significant byte first. The length field is the length of the data, not the data plus the length fields. This means an extra eight bytes per record are required. i.e.

```
data length length bytes of data data length
```

Formatted Direct

The record size is specified at open.

Unformatted Direct

The record size is specified at open.
C.9 Termination codes

There are various circumstances under which iserver can terminate. iserver 1.5 makes it possible for a controlling script to distinguish between the following cases:

- Terminated properly on receipt of an `sps.success` token.
- Terminated properly on receipt of an `sps.failure` token.
- Terminated properly with any other value.
- Terminated on receipt of a user break.
- Terminated on seeing the transputer error flag set.
- Any other termination.

The values used are shown in Table C.4.

<table>
<thead>
<tr>
<th>Host</th>
<th>Termination</th>
<th>User Break</th>
<th>Error Flag</th>
<th>Any Other</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Success   Failure</td>
<td>Other</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MS-DOS</td>
<td>0         255       exit code 254</td>
<td>253</td>
<td>252</td>
<td></td>
</tr>
<tr>
<td>Helios</td>
<td>0         255       exit code 254</td>
<td>253</td>
<td>252</td>
<td></td>
</tr>
<tr>
<td>VAX/VMS</td>
<td>1 success 4  fatal</td>
<td>exitcode x 16 warning 10 information 2  error 12  fatal</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SunOS</td>
<td>0         255       exit code 254</td>
<td>253</td>
<td>252</td>
<td></td>
</tr>
</tbody>
</table>

Table C.4 iserver termination codes

The values chosen for VAX/VMS have been designed to generate different 'classes' of error.

Under all operating systems apart from VAX/VMS, error codes between 240 and 255 are reserved for use by iserver.
D ITERM files

This appendix describes the format of ITERM files; it is included for people who need to write their own ITERM because they are using terminals that are not supported by the standard ITERM file supplied with the toolset.

Standard ITERM files for this release are provided in the terms directory, which is a subdirectory of the main toolset installation directory. These files may be used as templates and tailored to suit your own needs. It is recommended that the installation files are not changed in any way, and that modifications are only made to copies of the files.

D.1 Introduction

ITERMs are ASCII text files that describe the control sequences required to drive terminals. Screen oriented applications that use ITERM files are terminal independent.

ITERM files are similar in function to the UNIX termcap database and describe input from, as well as output to, the terminal. They allow applications that use function keys to be terminal independent and configurable.

Within the toolset, the ITERM file is only used by the debugger tool idebug and the T425 simulator tool isim.

A default ITERM file may be defined in the TERM environment variable. For details see section D.8 and the Delivery Manual for the release.

D.2 The structure of an ITERM file

An ITERM file consists of three sections. These are the host, screen and keyboard sections. Sections are introduced by a line beginning with the section letters 'H', 'S' or 'K'. Case is unimportant and the rest of the line is ignored. Sections consist of a number of lines beginning with a digit. A section is terminated by a line beginning with the letter 'E'. The host section must appear first; other sections may appear in any order in the file. Sections must be separated by at least one blank line.

The syntax of the lines that make up the body of a section is best described in an example:

3:34,56,23,7. comments

Each line starts with the index number followed by a colon and a list of numbers separated by commas. Each line is terminated by a full stop ('.') and anything
following it is treated as a comment. Spaces are not allowed in the data string and an entry cannot be split across more than one line.

Comment lines, beginning with the character ‘#’, may be placed anywhere in an ITERM file. Extra blank lines in the file are ignored.

The index numbers in each section correspond to an agreed meaning for the data. In the following sections the meaning of the data in each of the three sections is described in detail.

D.3 The host definitions

D.3.1 ITERM version

This item identifies an ITERM file by version. It provides some protection against incompatible future upgrades.

   e.g. 1:2.

D.3.2 Screen size

This item allows applications to find out the size of the terminal at startup time. The data items are the number of columns and rows, in that order, available on the current terminal.

   e.g. 2:80,25.

Screen locations should be numbered from 0, 0 by the application. Terminals which use addressing from 1, 1 can be compensated for in the definition of goto X, Y.

D.4 The screen definitions

The lists of values in the screen section represent control codes that perform certain operations; the data values are ASCII codes to send to the display device.

ITERM version 2 defines the indices given in table D.1. These definitions are used in the example ITERM file; for a complete listing of the file see section D.8.

<td>home and clear screen</td>
</tr>
<tr>
<td>20</td>
<td>enhance on (not used)</td>
</tr>
<tr>
<td>21</td>
<td>enhance off (not used)</td>
</tr>
</tbody>
</table>

Table D.1 ITERM screen operations

For example, an entry like: ‘8:27,91,75.’ indicates that an application should output the ASCII sequence ‘ESC [ K’ to the terminal output stream to clear to end of line.

D.4.1 Goto X Y processing

The entry for 5, ‘goto X Y’, requires further interpretation by the application. A typical entry for ‘goto X Y’ might be:

5:27,-11,32,-21,32

The negative numbers relate to the arguments required for X and Y.

..., -ab, nn, ...

where: a is the argument number (i.e. 1 for X, 2 for Y).

b controls the data output format.

If b =1 output is an ASCII byte (e.g. 33 is output as !).

If b =2 output is an ASCII number (e.g. 33 is output as 33).

nn is added to the argument before output.

As a complete example, consider the following ITERM entry in the screen section:

5:27,91,-22,1,59,-12,1,72. ansi cursor control

This would instruct an application wishing to move the terminal cursor to X=14, Y=8 (relative to 0,0) to output the following bytes to the screen:

Bytes in decimal: 27 91 57 59 49 53 72
Bytes in ASCII: ESC [ 9 ; 1 5 H
D.5  The keyboard definitions

Each index represents a single keyboard operation. The data specified after each index defines the keystroke associated with that operation. Multiple entries for the same index indicate alternative keystrokes for the operation.

ITERM version 2 defines the indices given in table D.2. These definitions are used in the example ITERM file; for a complete listing of the file see section D.8.

</tbody>
</table>

Table D.2  ITERM key operations

D.6  Setting up the ITERM environment variable

To use an ITERM the application has to find and read the file. An environment variable (or logical name on VMS) called ITERM should be set up with the pathname of the file as its value.

For more details about setting environment variables see the Delivery Manual that accompanies the release.
D.7 ITERM files supplied with a toolset

The following ITERM files are supplied with the toolset:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ansi.itm</td>
<td>Generic ANSI iterm</td>
</tr>
<tr>
<td>ncd.itm</td>
<td>NCD X terminal iterm</td>
</tr>
<tr>
<td>necansi.itm</td>
<td>NEC PC iterm</td>
</tr>
<tr>
<td>pcansi.itm</td>
<td>PC iterm (requires ANSI.SYS)</td>
</tr>
<tr>
<td>sun.itm</td>
<td>SunView iterm</td>
</tr>
<tr>
<td>vt100.itm</td>
<td>vt100 iterm</td>
</tr>
</tbody>
</table>

Table D.3 ITERM files supplied

ansi.itm is likely to be the most portable in that it will work unchanged with most hosts. However, because of this it may only use the normal (alpha–numeric keys) of a keyboard. This means that some keys (when used in conjunction with the CNTL or SHIFT key) are associated with more than one operation. Specific host iterm files make use of known function keys etc. which leads to less overloading of keys.

Each iterm file may be treated as an example; you may create and use your own iterm file if you wish.
D.8 An example ITERM

This is the generic toolset ITERM file for an ANSI terminal.

# idebug key that isn't really part of ITERM but its here all the same!
#

# INTERRUPT CTRL A -- IDEBUG

# THAT'S ALL FOLKS
E Bootstrap loaders

E.1 Introduction

Special loading procedures can be created for the program and used in place of, or in addition to, the standard INMOS bootstrap. The file containing the new bootstrap is specified by invoking the collector with the ‘B’ and ‘T’ options.

User defined bootstraps must perform all the necessary operations to initialize the transputer, load the network, and set up the software environment for the application program.

Bootstraps are output to the program bootable file as the first section of code in the bootable file. The bootstrap, consisting of the primary and secondary bootstrap sequences, is followed by the standard INMOS network loader program, which is output in small packets, each packet consisting of a maximum of 60 bytes. The last packet of the network loader is followed by a length byte of zero.

In most cases a custom bootstrap will interface directly with the standard INMOS Network Loader, which places various pieces of code and data within the transputer memory in a controlled way. However, it is possible to skip the standard loader by sinking its code packets and following the commands used by the network loader that are output after the network loader.

The general format of a custom bootstrap is a concatenated sequence of bootstrap code segments each preceded by a length byte. The sequence can be any length. The bootstrap program must be contained in a single file.

The source of the standard INMOS Network Loader is supplied with the toolset and is fully commented. See the accompanying Delivery Manual for details of source directories supplied.

E.1.1 The example bootstrap

The example bootstrap loader provided on the toolset examples directory is a combination of several files used in the standard INMOS bootstrap scheme. The files have been combined into a single file to illustrate how to create a user-defined bootstrap; the functionality is the same as that used in the the standard INMOS scheme based on multiple files.

The program is written in transputer code and consists of two parts:

- *Primary* bootstrap – performs processor setup operations such as initializing the transputer links
• Secondary bootstrap – sets up the software environment and interfaces to the Network Loader.

Transfer of control

The calling sequence in the standard INMOS scheme is as follows:

The primary loader calls the secondary loader, which then calls the Network Loader. When the Network Loader has completed its work control returns to the secondary loader, which calls the application program via data set up by the Network Loader.

Custom bootstraps should follow the same sequence.

E.1.2 Writing bootstrap loaders

Bootstrap loader programs should be written to perform the same operations as the standard scheme, that is, hardware initialization, setting up the software environment, and calling the Network Loader. If you skip the Network Loader by sinking its code bytes then you must ensure its function is reproduced in your own code. If you do use the Network Loader you must ensure the interface to it is correct by setting up the invocation stack. The method by which this is achieved can be deduced from the example program source.

If you wish to make only a few small changes to the standard loader, for example, insert code to initialize some D-to-A convertors, then the example code can be used and the required code can be inserted between the Primary and Secondary Loader code as an additional piece of bootstrap code in the sequence of bootstraps. The rest of the code can be used as it stands.

If you decide to devise your own loading scheme and rewrite the Primary and Secondary Loaders then you should be familiar with the design of the Transputer and its instruction set. For engineering data about the transputer consult the 'Transputer Databook' and for information about how to use the instruction set see the 'Transputer Instruction Set: a compiler writer’s guide'.
